Neither DOER nor the other agencies, companies and individuals contributing to or assisting in the preparation of this document make any warranty, guarantee or representation (express or implied) with respect to the usefulness or effectiveness of any information presented in this document, nor assume any liability for damages arising from the use of this document.

This Guide is not intended to be an installation manual or a replacement for approved codes and standards, but rather is intended to create a common knowledge base of EV requirements for stakeholders involved in the development of EV charging infrastructure. EVs have unique requirements that differ from internal combustion engine (ICE) vehicles, and many stakeholders currently are not familiar with these requirements.
# Electric Vehicle Charging Infrastructure Deployment Guide - 2011

Charging station (free Juice bar) at the Charles Hotel in Cambridge, MA.
1. Introduction

In the early years of the automobile industry -- around the turn of the century -- battery-powered electric vehicles (EVs) were quite popular. More than 360 electric recharging stations dotted the landscape in and around Boston alone! Despite the advantages of reduced air pollutants, convenience, and virtually silent driving, electric vehicles fell from favor because of their slow acceleration, low speeds, and limited range between battery recharges.

This is no longer the case with EVs. A new generation of electric vehicles has come to market with the technical sophistication and performance able to serve the needs of many of today’s drivers. Most drivers (78%) commute less than 40 miles per day and the most recent national statistics (1995) show that the U.S. average person-miles per day is 39.1 Industry has received over two billion dollars from the federal government and is investing in EVs that meet commuter and driving needs as well as provide jobs for battery and car production in the U.S. These vehicles will deliver to the public lower fuel and maintenance costs, reduced pollution and reduce reliance on foreign oil.

Massachusetts is committed to a clean environment and EVs will play an important part in our implementation of the 2008 Global Warming Solutions Act and the Green Communities Act. In addition the State has adopted zero emissions vehicle regulations which requires auto manufacturers to sell at least 11 percent of their total vehicle sales “zero emission vehicles” (ZEV), such as electric vehicles with increasing percentages through model year 2018.

As the EV industry reemerges in the beginning of the 21st century, the development of an infrastructure for recharging at home, at work, and at public locations has developed as an imperative need. Generally, EV charging infrastructure consists of three components:

1. electrical service from the local utility,
2. on-site wiring, and
3. charging stations.

Because electrical service is available almost everywhere, the widespread development of EV charging stations is technically feasible. The New England bulk electricity supply system can generally meet the demand for power, and the utilities are involved with us in ensuring that local distribution issues are minimized. For installation of EVSE to occur, EV users will need to learn about the EV Equipment and the requirements for proper installation - subjects covered in this guide. Users of EV charging equipment can be assured that EVSE is designed with multiple safety features, preventing the possibility of electric shock, even if the person charging the vehicle is exposed to rain, snow, or inadvertently touches the EVSE connector.

In most cases, EV owners seek the economy and convenience of on-premises charging facilities and will have to assume responsibility for installing the EVSE. While the process of installing the EVSE at a home or business is not complicated, important procedures must be followed.

---

We hope this guide will increase understanding of the Battery electric cars and how they work with an EVSE to make installation easier.

2. Electric Vehicle Technology/configurations

This section describes the basic EV car and light and medium duty truck technologies that are either available in the marketplace or coming to market in the near future. The focus of this section is on street-legal vehicles that incorporate a battery energy storage device that can connect to the electrical grid for the supply of some or all of its fuel energy requirements.

There are two main vehicle configurations and the relative size of their battery packs are discussed in relationship to recommended charging infrastructure.

A. Battery Electric Vehicle (BEV)

_Battery Electric Vehicles_ (BEVs) are powered 100% by the battery energy storage system available on-board the vehicle. The Nissan LEAF is an example of a BEV. A BEV is refueled by connecting it to the electrical grid through a connector system that is designed specifically for this purpose. Most advanced BEVs have the ability to recapture some of the energy storage utilized through regenerative braking (in simple terms, the propulsion motor acts as a generator during braking). When regenerative braking is applied, BEVs can typically recover 5 to 15 percent of the energy used to propel the vehicle to the vehicle speed prior to braking. Sometimes manufacturers install solar photovoltaic (PV) panels on vehicle roofs. This typically provides a very small amount of energy relative to the requirements of propelling the vehicle, but integrating PV in the roof typically can provide enough power to operate some small accessory loads, such as a radio.

A typical BEV is shown in the block diagram in Figure 2-1. Since the BEV has no other significant energy source, a battery must be selected that meets the BEV range and power requirements. BEV batteries are typically an order of magnitude larger than the batteries in hybrid electric vehicles and are generally found in the vehicle’s trunk.

![Typical Battery Electric Vehicle](image-url)
B. Plug –in Electric vehicles (PHEV)

PHEVs are powered by two energy sources. The typical PHEV configuration utilizes a battery and an internal combustion engine (ICE) powered by either gasoline or diesel. Within the PHEV family, there are two main design configurations, a *Series Hybrid*, as depicted in Figure 2-2, and a *Parallel Hybrid*, as depicted in Figure 2-3.

The Series Hybrid vehicle is propelled solely by the electric drive system, whereas the Parallel Hybrid vehicle is propelled by both the ICE and the electric drive system. As with a BEV, a Series Hybrid will typically require a larger and more powerful battery than a Parallel Hybrid vehicle in order to meet the performance requirements of the vehicle solely based on battery power.

Manufacturers of PHEVs use different strategies in combining the battery and ICE. For example, the Chevy Volt utilizes the battery only for the first 40 miles, with the ICE generating electricity for the duration of the vehicle range. Other PHEVs may use the battery power for sustaining motion and the ICE for acceleration or higher-energy demands at highway speeds. Frequently,
the vehicles employing the first strategy gain a designation such as “PHEV-20” to indicate that the first 20 miles are battery only. Other terms related to PHEVs may include Range Extended Electric Vehicle (REEV) or Extended Range Electric Vehicle (EREV).

C. Batteries

1. Battery Technology: Recent advancements in battery technologies will allow EVs to compete with ICE vehicles in performance, convenience, and cost. Although lead-acid technology serves many EV applications like forklifts and airport ground support equipment very cost-effectively, the limitations on energy density and repeated cycles of charging and discharging make its application to on-road highway speed EVs less practical. Today, most major car companies utilize nickel-metal-hydride or various lithium-based technologies for their EVs. Lithium provides four times the energy of lead-acid and two times that of nickel-metal-hydride. The materials for lithium-based batteries are generally considered abundant, non-hazardous, and lower cost than nickel-based technologies. The current challenge with lithium-based technologies is increasing battery capacity while maintaining quality and cycle life and lowering production costs. From an infrastructure standpoint, it is important to consider that as battery costs are driven down over time; auto manufacturers will increase the size of the lithium-based battery packs, and thus extend the range of electric vehicles.

2. Relative Battery Capacity: Battery size, or capacity, is measured in kilowatt hours (kWh). Battery capacity for electric vehicles will range from as little as 3 kWh to as large as 40 kWh or more. Typically, PHEVs will have smaller battery packs because they have more than one fuel source. BEVs rely completely on the storage from their battery pack for both range and acceleration and therefore require a much larger battery pack than a PHEV for the same size vehicle.

3. Battery charging Times: The amount of time to fully charge an EV battery is a function of the battery size and the amount of electric power or kilowatts (kW) that an electrical circuit can deliver to the battery. Larger circuits, as measured by voltage and amperage, will deliver larger amounts of kW. The common 120 volts AC (VAC), 15 amp circuit will deliver at minimum 1.2 kW to a battery. A 240 VAC, 40 amp circuit (similar to the circuit used for household appliances like dryers and ovens) will deliver at minimum 6.5 kW to a battery. Table 2-1 provides information on several different on-road highway speed electric vehicles, their battery pack size, and charge times at different power levels to replenish a depleted battery. EV owners should check with their manufacturers for more specific charging time requirements for their vehicle.

Table 2-1 EV Charge Times

<td>------------------</td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
Charging times for the Nissan Leaf according to the manufacturer:
It takes about ~30 minutes to 80% at a 480 volt quick-charge station. Starting from a depleted battery, ~7 hours at 220/240V (depending on amperage), about 20 hours at 110/120V.

D. Auto Manufacturer Plans for EV production
President Obama hopes that the US will have 1 million EV/PEVs on the road by 2015. Many automakers have announced plans for the introduction of on-road highway speed EVs in the near future. Nissan, Ford, GM, BMW, Think, Mitsubishi, Chrysler, Mercedes, and Tesla all have plans for the manufacture of EV vehicles The market is changing very rapidly. Each manufacturer has a web site and by accessing this information, one can look at EV availability for both personal and fleet use.

3. Electric Vehicle Charging Stations

This section covers the terminology and general requirements of Electric Vehicle Supply Equipment (EVSE). EVSE provides for the safe transfer of energy between electric utility power and an electric vehicle.

Level 2 home charger by AV

A. Vehicle Charging Components
Power is delivered to the EV’s onboard battery through the EV inlet to the charger. The charger converts Alternating Current (AC) from the home or site to the Direct Current (DC) required to charge the battery in the vehicle. The charger and EV inlet are considered part of the EV. A connector is a device that, by insertion into an EV inlet, establishes an electrical connection to the electric vehicle for the purpose of charging and information exchange. The EV inlet and connector together are referred to as the coupler. The EVSE consists of the connector, cord, and interface to utility power. The interface between the EVSE and utility power will be directly “hardwired” to a control device, as illustrated in Figure 3-1, or a plug and receptacle, as illustrated in Figure 3-3. During the 1990’s, there was no consensus on EV inlet and connector design. Both conductive and inductive types of couplers were designed and in both cases, different designs of each type were provided by automakers. At the present time, however, the Society of Automotive Engineers (SAE) has agreed that all vehicles produced by automakers in the United States will conform to a single design, known as the J1772 Standard.

Cold temperatures can cause cords to freeze to the parking surface, so cord support should be considered.

ADA Compliance: Connector and receptacle heights, special curb cutouts, and disabled parking access are some of the measures that may be necessary to make a charging station fully accessible for the disabled. Each operator must assess their compliance with the federal Americans with Disabilities Act, as well as state and company policies regarding disabled access.
B. J1772 Coupler:

The J1772 Standard EV coupler is designed for 10,000 connections and disconnections with exposure to dust, salt, and water; is able to withstand a vehicle driving over it; and is corrosion resistant.

The J1772 Standard and National Electrical Code (NEC) requirements create multiple safety layers for EV components, including:

- The EV coupler
  - is engineered to prevent inadvertent disconnection.
  - has a grounded pole that is the first to make contact and the last to break contact.
  - has an interlock device that prevents vehicle startup while connected.
  - is unique to EV charging and cannot be used for other purposes.

- The EV inlet
  - is de-energized until it is attached to the EVSE.
  - will de-energize prior to removal of the connector.

The J1772 coupler and EV inlet will be used for both Level 1 and Level 2 charging, which are described below.

C. Charging Station Levels

In 1991, the Infrastructure Working Council (IWC) was formed by the Electric Power Research Institute (EPRI) to establish consensus on several aspects of EV charging. Charging levels were defined by the IWC, along with the corresponding functionality requirements and safety systems. EPRI published a document in 1994 that describes the consensus items of the IWC4.
Note: For Levels 1 and 2, the conversion of the utility AC power to the DC power required for battery charging occurs in the vehicle’s on-board charger. In DC Fast Charging, the conversion from AC to DC power typically occurs off-board, so that DC power is delivered directly to the vehicle.5

**Level 1 – 120 volt AC**
The Level 1 method uses a standard 120 volts AC (VAC) branch circuit, which is the lowest common voltage level found in both residential and commercial buildings. Typical voltage ratings can be from 110 – 120 volts AC. Typical amp ratings for these receptacles are 15 or 20 amps. A 15 amp charge takes twice as long as a 20 amp outlet.

EV suppliers will provide a Level 1 Cord Set (120 VAC, 15 or 20 amps) with the vehicle. The Cord Set will use a standard 3-prong plug (NEMA 5-15P/20P) with a charge current interrupting device (CCID) located in the power supply cable within 12 inches of the plug. The vehicle connector at the other end of the cord will be the design identified in the J1772 Standard. This connector will mate properly with the vehicle inlet, also approved by J1772. Because charge times can be very long at Level 1 (see Table 2-1), many EV owners will be more interested in Level 2 charging at home and in publicly available locations. Some EV manufacturers suggest their Level 1 Cord Set should be used only during unusual circumstances when Level 2 EVSE is not available, such as when parked overnight at a non-owner’s home.
Several companies provide kits to convert ICE and hybrid vehicles to plug-in vehicles. Many of these conversions use a standard 3-prong electrical plug and outlet to provide Level 1 charging to their vehicles. With the standardization of EVs on the J1772 Standard and the higher level of safety afforded by a J1772-compliant charging station, existing vehicles will need to be retrofitted to accommodate a J1772 inlet in order to take advantage of the deployment of EVSE infrastructure.

**Level 2 – 240 volt AC**

Level 2 is typically described as the “primary” and “standard” method for the EVSE for both private and publicly available facilities. This method specifies a single-phase branch circuit with typical voltage ratings from 220 – 240 volts AC. The J1772-approved connector allows current as high as 80 amps AC (100 amp rated circuit). However, current levels that high are rare, and a more typical rating would be 40 amps AC, which allows a maximum current of 32 amps. This provides approximately 7.7 kW with a 240 VAC circuit.

The higher voltage of Level 2 allows a much faster battery charge. Because of the higher voltage, Level 2 has a higher level of safety requirements than Level 1 under the NEC, including the requirement that the connector and cord be hardwired to the control device and premises wiring, as illustrated in Figures 3-1 and 3-5.

**DC Fast Charging and Level 3 (no Standard as of this printing)**

DC Fast Charging was developed for commercial and public applications, and is intended to perform in a manner similar to a commercial gasoline service station in that recharge is rapid. Typically, DC Fast Charging would provide a 50% recharge in 10 to 15 minutes. DC Fast Charging typically uses an off-board charger to provide the AC to DC conversion. The vehicle’s on-board battery management system controls the off-board charger to deliver DC directly to the battery. The off-board charger is serviced by a three-phase circuit at 208, 480, or 600VAC.
The SAE standards committee is working on a higher-powered J1772 Level 3 method, but placed the highest priority on approving the J1772 Level 1 and 2 connector first. The Level 3 standard is expected to be approved in 2011 – 2012.

Figure 3-5

Note: Although it is uncommon, a vehicle manufacturer may choose not to incorporate an on-board charger for Levels 1 and 2, and instead utilize an off-board DC charger for all power levels. In this case, the EV would only have a DC charge port. Another potential configuration that may be found, particularly with commercial vehicles, is providing 3-phase power directly to the vehicle. This configuration requires dedicated charging equipment that will not be compatible with typical publicly available infrastructure.

D. Charging level considerations Level 1 versus Level 2
For a BEV owner (and some PHEV owners who choose the utility time of use rates), the preferred method of residential charging will be Level 2 (240VAC/single phase power) in order to provide a reasonable charge time and to also allow the local utility the ability to shift load as necessary while not impacting the customer’s desire to obtain a full charge by morning. For other PHEV owners, a dedicated Level 1 circuit may adequately meet the owner’s charging needs. Level 1 will suffice for some BEV owners who have the opportunity for Level 2 charging at work or in public areas, as they may find the vehicle battery remains at a higher charge and thus home charging time is not a concern. See Table 2-1 for relative battery sizes and estimated recharge times. Depending on the amperage of your home electrical service you will be able to use appliances at the same time when you are charging your vehicle. 

This is why it is strongly recommended that one has a licensed electrician evaluate one’s house’s readiness to install an EVSE. This electrician can also advise you on the best and lowest cost location for the EVSE.

E. Installation of EVSE code and UL information.

EVSE level 2 models selected must be:
- UL certified.
- Installed by a Massachusetts licensed electrician.
Electric Vehicle Charging Infrastructure Deployment Guide - 2011

- Installed in compliance with NFPA 70, National Electric code article 625 and applicable Massachusetts electrical code adopted and enforced within the jurisdiction of installation.

It is suggested that the utility supplying power to the installation site be contacted to ensure adequate power supply to the site. This may become standard procedure as more EVSEs are installed in a neighborhood or in district with heavy power demands.

Installation is generally straightforward and under state permitting laws each City or Town is required to issue a permit to install a device within 5 days from request and then upon completion of the work the Town or City must inspect the completed job within 5 days.

F. NEC 625 code information. This is the 2008 code soon to be adopted in the 2011 code.

### Ch 625 - Electric Vehicle Charging Infrastructure

#### 625.15 Markings
The electric vehicle supply equipment shall comply with 625.15(A) through (C).

(A) General. All electric vehicle supply equipment shall be marked by the manufacturer as follows:

FOR USE WITH ELECTRIC VEHICLES

(B) Ventilation Not Required. Where marking is required by 625.29(C), the electric vehicle supply equipment shall be clearly marked by the manufacturer as follows:

VENTILATION NOT REQUIRED

The marking shall be located so as to be clearly visible after installation.

(C) Ventilation Required. Where marking is required by 625.29(D), the electric vehicle supply equipment shall be clearly marked by the manufacturer, “Ventilation Required.” The marking shall be located so as to be clearly visible after installation.

#### 625.16 Means of Coupling
The means of coupling to the electric vehicle shall be either conductive or inductive. Attachment plugs, electric vehicle connectors, and electric vehicle inlets shall be listed or labeled for the purpose.

#### 625.17 Cable
The electric vehicle supply equipment cable shall be Type EV, EVJ, EVE, EVJE, EVT, or EVJT flexible cable as specified in Article 400 and Table 400.4. Ampacities shall be as specified in Table 400.5(A) for 10 AWG and smaller, and in Table 400.5(B) for 8 AWG and larger. The overall length of the cable shall not exceed 7.5 m (25 ft) unless equipped with a cable management system that is listed as suitable for the purpose. Other cable types and assemblies listed as being suitable for the purpose, including optional hybrid communications, signal, and optical fiber cables, shall be permitted.

#### 625.18 Interlock
Electric vehicle supply equipment shall be provided with an interlock that de-energizes the electric vehicle connector and its cable whenever the electrical connector is uncoupled from the electric vehicle. An interlock shall not be required for portable cord-and-plug-connected electric vehicle supply equipment intended for connection to receptacle outlets rated at 125 volts, single phase, 15 and 20 amperes.

#### 625.19 Automatic De-Energization of Cable
The electric vehicle supply equipment or the cable-connector combination of the equipment shall be provided with an automatic means to de-energize the cable conductors and electric vehicle connector upon exposure to strain that could result in either cable rupture or separation of the cable from the electric connector and exposure of live parts. Automatic means to de-energize the cable conductors and electric vehicle connector shall not be required for portable cord-and-plug connected electric vehicle supply equipment intended for connection to receptacle outlets rated at 125 volts, single phase, 15 and 20 amperes.

#### 625.21 Over current Protection
Over current protection for feeders and branch circuits supplying electric vehicle supply equipment shall be sized for continuous duty and shall have a rating of not less than 125 percent of the maximum load of the electric vehicle supply equipment. Where noncontiguous loads are supplied from the same feeder or branch circuit, the over current device shall have a rating of not less than the sum of the noncontiguous loads plus 125 percent of the continuous loads.

#### 625.22 Personnel Protection System
The electric vehicle supply equipment shall have a listed system of protection against electric shock of personnel. The personnel protection system shall be composed of listed personnel protection devices and constructional features. Where cord-and-plug-connected electric vehicle supply equipment is used, the interrupting device of a listed personnel protection system shall be provided and shall be an integral part of the attachment plug or shall be located in the power supply cable not more than 300 mm (12 in.) from the attachment plugs.

#### 625.23 Disconnecting Means
For electric vehicle supply equipment rated more than 60 amperes or more than 150 volts to ground, the disconnecting means shall be provided and installed in a readily accessible location. The disconnecting means shall be capable of being locked in the open position. The provision for locking or

<tr>
<td><strong>625.29</strong></td>
<td><strong>Indoor Sites</strong> Indoor sites shall include, but not be limited to, integral, attached, and detached residential garages; enclosed and underground parking structures; repair and nonrepair commercial garages; and agricultural buildings. (A) Location. The electric vehicle supply equipment shall be located to permit direct connection to the electric vehicle. (B) Height. Unless specifically listed for the purpose and location, the coupling means of the electric vehicle supply equipment shall be stored or located at a height of not less than 450 mm (18 in.) and not more than 1.2 m (4 ft) above the floor level. (C) Ventilation Not Required. Where electric vehicle nonvented storage batteries are used or where the electric vehicle supply equipment is listed or labeled as Suitable for charging electric vehicles indoors without ventilation and marked in accordance with 625.15(B), mechanical ventilation shall not be required. (D) Ventilation Required. Where the electric vehicle supply equipment is listed or labeled as suitable for charging electric vehicles that require ventilation for indoor Charging, and is marked in accordance with 625.15(C), mechanical ventilation, such as a fan, shall be provided. The ventilation shall include both supply and Exhaust equipment and shall be permanently installed and located to intake from, and vent directly to, the outdoors. Positive pressure ventilation systems shall be Permitted only in buildings or areas that have been specifically designed and approved for that application. Mechanical ventilation requirements shall be determined By one of the methods specified in 625.29(D)(1) through (D)(4). (1) Table Values. For supply voltages and currents specified in Table 625.29(D)(1) or Table 625.29(D)(2), the minimum ventilation requirements shall be as Specified in Table 625.29(D)(1) or Table 625.29(D)(2) for each of the total number of electric vehicles that can be charged at one time. (2) Other Values. For supply voltages and currents other than specified in Table 625.29(D)(1) or Table 625.29(D)(2), the minimum ventilation requirements shall be Indoor sites(con’t) Calculated by means of general formulas stated in article 625.39(D) (2). (3) Engineered Systems. For an electric vehicle supply equipment ventilation system designed by a person qualified to perform such calculations as an integral part Of a building’s total ventilation system, the minimum ventilation requirements shall be permitted to be determined per calculations specified in the engineering study. (4) Supply Circuits. The supply circuit to the mechanical ventilation equipment shall be electrically interlocked with the electric vehicle supply equipment and shall Remain energized during the entire electric vehicle charging cycle. Electric vehicle supply equipment shall be marked in accordance with 625.15. Electric vehicle supply equipment receptacles rated at 125 volts, single phase, 15 and 20 amperes shall be marked in accordance with 625.15(C) and shall be switched, and the Mechanical ventilation system shall be electrically interlocked through the switch supply power to the receptacle.</td>

</table>
(A) Location. The electric vehicle supply equipment shall be located to permit direct connection to the electric vehicle.
(B) Height. Unless specifically listed for the purpose and location, the coupling means of electric vehicle supply equipment shall be stored or located at a height of not less than 600 mm (24 in.) and not more than 1.2 m (4 ft) above the parking surface.

G. Programming the EVSE

- Some Level 2 EVSE suppliers will provide controls in the EVSE to allow charging at programmable times to take advantage of off-peak power pricing. If not, homeowners may wish to install a timer device in this circuit to control charging times. Check with your utility about off-peak power pricing.

The specific steps involved in this process are shown in the flowchart below. In general, they include:

Figure 5: Residential EVSE Installation Flowchart

1. Visit Auto dealer and chose which EV to purchase.
2. Decide if you want to install a level 2 charger at home.
3. If installing a charger contact licensed electrical for site visit to determine if your service can handle the installation of a charger and also determine the best location for the unit.
4. If power is adequate and location is determined then hire licensed electrician to pull a permit and install the unit.
