INTRODUCTION

In the United States, one of every 33 infants is born with a birth defect. Although birth defects are rare when compared to other adverse birth outcomes, such as low birth weight or prematurity, they are the leading cause of death in the first year of life. Nationally, about 20% of all infant deaths are attributable to birth defects (abnormalities of structure, function or metabolism present before birth). Birth defects may also result in mental or physical disability. Some require costly medical care and cause great distress in families. The economic, emotional, and social impact on families is frequently catastrophic.

The causes of many birth defects are poorly understood. Certain genetic and environmental factors have been implicated in selected birth defects. These include prenatal environmental factors (such as infections), exposures to medications or other chemicals, drug or alcohol abuse, and nutritional deficiencies. Some birth defects can be caused by a single abnormal gene, while other birth defects arise due to a complex interplay between various genetic and environmental factors.

Studies have shown that the presence of adequate amounts of folic acid (vitamin B9) in the mother’s system before conception and during the first trimester may help prevent birth defects of the brain and spinal cord known as neural tube defects. Folate supplementation may also reduce risks of certain other birth defects.

For more than 70% of all birth defects, however, no known cause has been identified. Researchers are investigating a wide variety of environmental exposures (to the mother and fetus) and other risk factors as possible causes, with a focus on the month before and three months after conception.

BIRTH DEFECTS IN MASSACHUSETTS

In Massachusetts, birth defects are the leading cause of infant death and substantially contribute to prematurity. Among live births and stillbirths to Massachusetts residents in 2004-2005, 2,590 (2,536 live births and 54 stillbirths) had one or more structural birth defects for a prevalence rate of 166.8 per 10,000 live births.

Cardiovascular birth defects are the most commonly occurring birth defects in both Massachusetts and the nation and contribute more to infant deaths than any
defects. Birth defect cases were 2.8 times more likely to have low birth weight (less than 2,500 grams) and 2.4 times more likely to be born premature compared to births without birth defects. Infants with birth defects were 12.4 times more likely to die before their first birthday compared to infants without birth defects. While numbers of infants with birth defects are relatively small, it is important to recognize the long-term medical, economic and human impact of these outcomes when diagnosing and treating a baby with a birth defect.

**Infant Sex**

The Massachusetts’ birth defect prevalence rates for 2004-2005 were 135.0 among females and 197.6 among males per 10,000 live births. While the prevalences of most types of birth defects did not substantially differ by sex of the infant or fetus, male infants uniquely had hypospadias, but they were also more likely than female infants to have obstructive genitourinary defects, Hirschsprung disease, clubfoot, polydactyly/syndactyly, and cleft lip with or without cleft palate.

Notably, in 2004-2005, birth defects were not reported in Massachusetts when they were prenatally diagnosed and the pregnancy was subsequently electively terminated. This selective ascertainment would tend to result in lower rates for Massachusetts for certain birth defects. Spontaneous deliveries of stillbirths greater than or equal to 20 weeks of gestation were reported by birthing hospitals. However, limited information about stillbirths is included in the maternal record. As a result, some birth defects in stillbirths are not well documented and are unable to be confirmed for inclusion in state as well as national surveillance.

**Maternal Age & Birth Defects**

The number of births to older mothers has been increasing over time in Massachusetts. There is a higher prevalence of birth defects and chromosomal defects in particular among mothers older than age 35.

Down syndrome and gastrochisis are two birth defects of interest in cases of relatively older or younger mothers, respectively.

**Birth Defects in Massachusetts vs the US**

Massachusetts has been one of 11 states with population-based monitoring programs to contribute birth defect data to the CDC’s published national prevalence estimates for 18 selected major birth defects. Massachusetts’ rates for 2004-2005 were significantly lower than US rates for about half of the birth defects and were about the same as the national estimates for the other half. Differences in surveillance system methodology and regional variation may account for the lower rates for some defects.

**Prevalence Rates for Massachusetts and the United States for Selected Birth Defects, 2004-2005**

Down syndrome and gastrochisis are two birth defects of interest in cases of relatively older or younger mothers, respectively.

**Down Syndrome**

As noted, there is a strong association established between the rate of Down Syndrome and advanced maternal age.
Although 45% of babies with Down syndrome were born to women under 35, the Down syndrome rate of 27.0 per 10,000 live births for women 35 years and older was about three times that of any other maternal age group.

**Gastroschisis**

On the other hand, gastroschisis is a defect that preferentially occurs among younger mothers, and is a condition of particular concern for that reason. In neonates with gastroschisis, the intestines—and sometimes other organs—protrude through a defect in the abdominal wall. During 2004-2005, younger mothers (age 19 and under) in Massachusetts had the highest rate (14.1 per 10,000 live births) of babies born with gastroschisis.

**Maternal Race / Hispanic Ethnicity**

In Massachusetts and nationally, the prevalences of some birth defects are similar across all race groups, but other birth defects appear to vary by maternal race and Hispanic ethnicity. Possible explanations for the differences include genetic variation, diet and lifestyle, and varying access to prenatal screening and health care services.

**Birth Defects by Massachusetts Region**

The Massachusetts Executive Office of Health and Human Services delineates regions for use by the Department of Public Health for statistical, care coordination, and administrative purposes. The birth defect prevalences in six Massachusetts regions were not statistically significantly different.

**Assisted Reproductive Technology**

The CDC reports that more than 1 percent of all infants today are conceived through assisted reproductive technology (ART). In 2005, Massachusetts was one of the five states with the highest frequencies of ART procedures performed, which may be due in part to more complete insurance coverage for ART in MA. Importantly, infants conceived by ART have been shown to be at two to four times greater risk for certain birth defects than infants conceived naturally.

**Multiple Births**

Birth defects are more common among multiple births (more than one fetus) than in singleton births, and the number of multiple births has been increasing over time in Massachusetts. The birth defect prevalence rate was 164.3 for singletons and 216.4 for multiple births per 10,000 live births. Birth defects that commonly occurred in multiple births included atrial septal defects, hypospadias, clubfoot, Down syndrome, and tetralogy of Fallot.

**The Financial Burden of Birth Defects**

A recent estimate of hospital costs during the first two years of life for Massachusetts children born between 1998 and 2004 with orofacial clefts was $10 million.
The Massachusetts combined lifetime costs for babies born with 12 major structural birth defects were an estimated $125 million in 2005 dollars.\textsuperscript{x} Nationally, the lifetime costs of 18 common birth defects have been estimated to be $11 billion.\textsuperscript{xi} These figures include direct costs of medical treatment, developmental services and special education, as well as indirect costs to society for lost wages due to early death or occupational limitations. Psychosocial costs are also of concern but are difficult to directly quantify.
