RE: Horseshoe Crab Quota Management Proposal

Dear Director McKiernan:

As the State Senator representing the City of New Bedford, I am writing to express my opposition to the proposed reallocation of horseshoe crab from the bait quota to the biomedical sector. After reviewing the proposed regulation, it remains unclear why the department would shift quota toward an industry that can already access additional crab through the so-called rent-a-crab process. In its proposal, the department cites an overabundance of bait with ample stock in frozen storage. However, no data is cited to support this assertion.

While reduction in crab mortality is a laudable goal, the biomedical processes remains a very traumatic experience involving the insertion of a needle into the crustacean's heart to drain its blood. Studies suggest that up to 30 percent of bled crab will later die while others will fail to spawn properly. Keeping an estimated 28,000 additional crab alive annually by shifting the quota does not necessarily equate to a significantly healthier population of horseshoe crab.

Furthermore, these proposed changes will likely inflict a negative impact upon conch fishermen already on the brink of survival. Horseshoe crab remains the primary bait source for these fishermen and Massachusetts remains one of the last fisheries available to them. The potential for economic ruin seems to outweigh the slight improvement in mortality rates for this species.

In closing, I respectfully oppose this proposal and recommend that the quota remain in its current form.

Sincerely,

Mark Montigny
SENATOR

THE GENERAL COURT OF MASSACHUSETTS
STATE HOUSE, BOSTON 02133-1053

March 5, 2026

Dear Esteemed Chair and Members of the Marine Fisheries Advisory Commission (MFAC):

We join the Massachusetts Conch Association in opposing the prohibition or any reduction in the use of Horseshoe Crabs as a bait source in Massachusetts.

There is no viable substitute for horseshoe crab as bait for the conch fishery. Most fishermen mix the horseshoe crab with other food sources as a regular sustainable, management practice. Once that quota is reduced it will never be restored. Several states have imposed either outright bans or severely reduced the harvest of horseshoe crabs. Obtaining horseshoe crabs for bait from other states is not an option. The conch fishermen currently only have one bait supply and that is from our own state waters. The industry opposes any changes in the current horseshoe crab bait fishery. The Horseshoe Crab population in Massachusetts is not only flourishing, but evidence shows that their numbers are increasing mainly because of existing regional, regulatory frameworks that have ensured sustainability.

The commercial bait industry depends heavily on limited, regulated horseshoe crab harvesting to sustain the whelk and eel fisheries; two important sectors of the Massachusetts coastal economy. Prohibiting the use of horseshoe crabs as bait would directly threaten the livelihoods of many local fishermen and small business owners who already face rising costs and declining stocks. In 2023, a similar proposal to restrict harvesting was rejected by a fisheries advisory commission after strong concerns were raised about the potential impact on these working families.

Conservation efforts should focus on balanced, science-based regulation that support both ecological preservation and economic vitality and include measures such as stricter seasonal limits, improved habitat protection, and collaborative research on the adoption of sustainable synthetic testing alternatives rather than outright bans that penalize responsible fishers. Tighter restrictions on bait harvesting risk constraining the overall crab population supply chain, increasing costs, and complicating access for biomedical use.

We urge the Commission to support promoting sustainable management practices, and better stakeholder cooperation versus a straight ban on the horseshoe crab bait source. Thank you for your time and consideration.

Sincerely,

REP. CHRIS HENDRICKS
11th Bristol District

REP. ANTONIO CABRAL
13th Bristol District

Subject: Horseshoe crab re allocation
To: <marine.fish@ma.gov>

Dear Drirector McKiernan,

My name is Colin Urquhart I am a fisherman out of New Bedford, I would like to first say congratulations to the DMF for creating a sustainable horseshoe crab harvest back in 2010 with the lunar calendar closures. HSC populations have been increasing since then.

Despite this great success, year after year, the beach pickers and conch fishermen are forced back here to defend their right to harvest a sustainably managed species. Two years ago 60,000* crabs were reallocated to the biomedical sector, and last year the historically successful lunar calendar closures were replaced with an all out spring closure. The impact on these two changes is yet to be seen but considering prior data already showed increasing populations, further reducing our bait quota feels unjustified.

The DMF has no ability to restrict HSC sales to only Massachusetts fishermen. If the 100,000 crabs is based on the estimated crabs use by Massachusetts fishermen during a low effort year, then theoretically the other 40,000 will be sold out of state or saved for spring conch potting since you've eliminated our ability to harvest bait in the spring. If next year we only get to harvest 100,000 crabs, the number that reaches Massachusetts fishermen will be less than that creating a local shortage assuming efforts remain the same and worse if efforts increase. Effort and consequently landings of conch have been low for a few years following increased gage sizes and a crash in the market caused by recession and trade issues, however there has been an uptick in price this year which will likely entice more effort if the trend continues. That is unless our bait quota is whittled away and we don't have enough HSCs to fish with. How would you feel if there was an increase in effort and there was a shortage of crabs for your Massachusetts fisherman.

As far as the repeated claims that the conch fishery is over fished, that at one point may have been true but it is not true in 2026. Your trawl surveys are not capable of adequately sampling a nocturnal, subterranean species during the day and since "DMF can't justify funding a proper conch pot population survey for a fishery only worth 1.5 million dollars." You have classified them over fished which has been used as ammunition against us.

In your letter to the Marine Fisheries Advisory Commission in November regarding the bills at the state house to outlaw horseshoe crab harvest you said," Banning bait harvest will have significant direct and indirect impacts to the Commonwealth's seafood industry. Although HSCs are not consumed by the public, their harvest and sale as bait are an important component to certain sectors of the commercial fishing economy. The cumulative impacts might be deleterious to the commercial fishing and seafood dealer sector, particularly along Cape Cod and the South Coast where most of the affected fisheries and processing activities occur, and negative impacts food production and seafood availability in the Commonwealth. You and your staff know that the horseshoe crab bait fishery is a key fishery in our state waters that supports not just the fishermen but a whole chain of dealers, processors, all the way to the end consumers. You folks also know with almost certainty that maintaining a 140,000 crab quota will not have adverse impacts on the population. This is 3 years in a row you have made a proposal to chip away our fishery. Reducing our quota based on your estimated HSC consumption from a low effort year with out ensuring the crabs go to Massachusetts fishermen in my opinion is inconsiderate management. Like always, surplus crabs will find a home out of state, and if our effort increases we have the wiggle room at 140,000 crabs to accommodate that. You should be proud that Massachusetts has such a sustainable fishery that we can help neighboring states that fell victim to the Audubon Society war machine. Im sure you are as sick and tired of defending a sustainable harvest as much as I am, and I believe a lot of your motivation for this proposal is to appease the bird people so please stand behind the fishermen, and the data, and don't reallocate any more of our bait quota away. In fact now that I think about it please roll back the spring pick!

Conchs are a species I would like to see my self fish for the rest of my life. After all the hard work yourself and the division has done to protect and bring back the conch fishery, it would be a shame to have it all be for nothing, without an adequate source of horseshoe crab bait there will be no conch fishery.

Thank you for your time
Colin Urquhart

This Is a Public Comment on the proposed rule changes for 2026.
1. Regarding the Summer Flounder fishery. I understand the thought process on these changes. I do think this could have a negative effect on price, but like you said in your report this has a lot to do with effort if let's say other fisheries are not targeted as in 2024. IN FAVOR

2.Sea Bass I would just like to say that I don't often catch over #100LB with the net but during squid season on a 1-3day trip this can happen and it would be great to utilize a multi day cumulative trip quota or large tow system where you call in to report a lets say #300 tow instead of just high grading and throwing #200 pounds back.

3.Horse Shoe Crab Bait Quota shift.
The Last few years for the Conch fishery has been an up and a down year fallowed by this past year having a rebound in landings and use of horse shoe crabs. The fishery uses an abundance of crabs in the fall and freezer space becomes limited mid summer. If the bio medical industry needs more crabs lets please keep the horse shoe crab bait quota at 140,000 and just make an increase to the biomedical 240,000. I saw an abundance of horse shoe crab in vineyard sound last summer and released 95% because of a poor bait price and not wanting to kill a cornerstone species for a miserable price. With conch hopes high I foresee a Stock piling of crab happening this year.
- To Increase good reporting data on horse shoe crab/bait skate and more for bait fishery implement automatic Bait dealer permit for certain bait potential permits so that no bait is sold without getting counted. Or just allow to be Entered just on Safis would be best when filing out the months catch reports. Without a bait dealer permit people like myself don't hardly have time for more paperwork so if its just a bait sale item on Safis at least it would be counted.
Question what does Biomedical Pay for Horse shoe Crab ?

Thanks for all of your time on these species,

Matthew Mayhew

March 6, 2026

Dear Director McKiernan,

My name is Celeste Howe. I am a resident of Barnstable and a friend of fisherman on Cape Cod.

I know fisherman to be great stewards of the sea who care about sustainability of all the species. Without this balance their industry would suffer.

I respectfully urge the Division to consider the cumulative impacts of recent management decisions of the horseshoe crabs and the data demonstrating the effectiveness of existing conservation measures before pursuing further reductions to the bait quota. Any consideration of reallocating quota toward biomedical purposes should account for the full context of the cumulative effects and include the historical role of horseshoe crab bait and it's importance in supporting food fisheries.

Thank you,

Celeste Howe

Dear DMF,

Thank you for the informational session on March 3rd and for the opportunity to comment.

From the information provided I learned that 3 separate organizations found a population increase in Massachusetts, 2025 data for the conch fishery has yet to be analyzed, and that Massachusetts is being presented with a substantial amount of additional fluke quota.

Fishers have made significant adjustments and sacrifices to ensure a healthy population of HSC's. Bait bags and smaller baits, lunar closures, reduced quotas and daily possession limits to name a few that contributed to the population increase.

Without the 2025 data being studied it would be impossible to make adjustments to the 2026 conch fishery. This fishery has historically been highly cyclical. As there is currently a downward trend there are upward trends. Without the information current, it would be impossible to see permit transfers, landings, and price. All which seem to have increased. The increasing HSC population helps this small but important fishery. The current bait quota is a reasonable amount to barely sustain the industry during good years.

Like the conch fishery, the fluke fishery is dependent on the current HSC quota. It is no secret, for the mobile gear fleet, a few of everything makes a days pay. It is important the fluke boats are be able to retain crabs as the State is faced with increased quotas.

For these reasons, I oppose proposals to decrease and reallocate the HSC quota. However, if the decision is made to do so, there must be the ability to easily and efficiently reanalyze and make adjustments.

Respectively,

David Meservey

Subject: Conched Out - Primary Buyer Status

Hi Matthew,

I'm following up on our recent phone conversation about the primary buyer status on your Wholesale Truck permit for Conched Out Fisheries LLC, MA Permit # 12704. As we discussed, the permit is not authorized to be a primary buyer (meaning purchase directly from commercial harvesters) of any species in Massachusetts because you do not have a permanent place of business in Massachusetts. I had said I would follow up with Massachusetts' primary buyer rules in writing.

In reference to dealers acting as primary buyers, Massachusetts regulation, 322 CMR 7.07(4)(a) states "**Dealers must have a permanent place of business in Massachusetts. Dealers shall maintain a written record at their Massachusetts place of business of all primary purchases of any species from commercial fishermen in Massachusetts.**" Additionally, the same criteria for primary buyers is described in the annual primary buyer application form.

Currently, your Wholesale Truck permit only allows you to purchase seafood from Massachusetts wholesale dealers and transport it. If you were to establish a permanent place of business in Massachusetts, we would be able to authorize your permit to be a primary buyer.

SAFIS dealer records indicate that you have been buying from Massachusetts boats in 2026. Please note that you are not authorized to do that at this time.

Please let me know if you have any questions.

Director Daniel McKiernan,

I believe that the horseshoe crab reallocation proposal is far too drastic of a change for the fishing industry at this time. It does not adequately addresses the by-catch needs of the mixed trawl fishery that takes place in the summer in Nantucket sound. By taking 40,000 crabs from the "bait fishery"(common pool that all permitted vessels can utilize) and shifting more quota to the directed biomedical fishery (private fishing quotas issued to only two entities) this proposal will almost certainly exasperate a situation where more targeted effort will be directed at horseshoe crabs by fewer boats. Meanwhile the rest of the fleet will have less crabs leading to regulatory discards while attempting to pursue other species. It could also lead to a shortage of bait in future years that the conch pot fishery heavily relies on. The fishery needs the 140,000 crabs currently allocated to allow for by-catch needs and anything less will negatively impact the intended conservation efforts that this proposal is attempting to achieve. Any transfer whether now or in the future needs to be set aside for by-catch purposes and not a directed fishery. For these reasons I am asking that you maintain status quo at this time.

I am asking that DMF hold a series of meetings to take a holistic view of the mixed trawl fishery and look at how the fishery as a whole operates currently as well as historically. I believe it is important that both the fishing and bio medical industries participate so that we can address the needs of both industries. We need to look at how all species are managed together and how the fleet has been spread out geographically in the past. For example changing conch regulations over the last 10-12 years have had a huge effect on how the fleet is distributed throughout the sound. These regulations have changed the distribution of the fleet so dramatically that they are significantly effecting horseshoe crab management, at the same time they have effectively ended the trawl fishery for conch. If DMF were willing to look at the mixed trawl fishery with an ecosystem based management approach as opposed to individually managing each species many conflicts could be easily resolved.

If dmf insists on moving forward with a quota transfer without addressing the underlying issues that the fishing industry is facing. I ask that safe guards be put in place as well as a sunset clause so that these issues can be properly addressed in the future. One safe guard that would help encourage utilization of by-catch would be to set equal trip limits for both bait and biomedical crabs and hold off on increasing the limits until September 1st or the day after the fluke fishery closes which ever occurs first. This would encourage more bait crabs to be bled through the rent a crab program as well as a higher number of boats to partner up with the biomedical industry during the height of the season. Thank you for taking the time to read my comment. I look forward to collaborating with DMF in the future.

Thank you
Andrew Walsh

ATTN: Dan McKiernan
Hello Dan, wanted to add a few things at the zoom public hearing but struggled with connecting the mic on iPhone. The Horseshoe crab presentation and the researched Data is detailed and looking very positive for the future and for the Industry. A few bullet points from my perspective to summarize.
* The Horseshoe crabs in Massachusetts are Not migratory, they do Not migrate out of MA state waters. Therefore, DMF is in total control of its management.

* The Horseshoe crab population in Massachusetts waters is healthy and is in good position to thrive. Enhanced recruitment will occur with the recent Spring spawning closure.

* Monitoring the Conch Pot Fishery usage of horseshoe crabs and making in-season adjustments if necessary during the season-a percentage baseline needs to be adopted for the bait and bio markets, to protect its quota shares.

* Dedicated research from DMF in determining the status of Massachusetts Horseshoe crabs is ranked 2nd only behind American lobsters of all the MA quota-managed species.

*Massachusetts Horseshoe crabs have been monitored and quota-managed since 1998. And the science, research, and monitoring/management continues to advance.
*The Red Knot bird is a late-summer/Autumn migratory species in Massachusetts. Therefore, is not a factor during the Massachusetts Horseshoe crab Spring spawning season. In fact, the Red Knot bird flys Northwest towards Hudson Bay and the Arctic when departing Delaware Bay(their Spring primary stop over location).

*The Massachusetts Division of Marine Fisheries are going above and beyond in their roles managing the status of Massachusetts Horseshoe crabs. Typically, in my 40 plus years as a commercial fisherman (past 23 years as a conch pot fisherman)-when a quota-managed species stock is increasing and healthy, the opportunities for commercial fisherman will increase. And when the resource is doing poorly, commercial fishing opportunities will decrease. Hence, the need to adopt conservation measures. The Black Sea Bass a good example. I can recall 2 or 3 consecutive seasons where the annual commercial harvest quota was 300,000 lbs or less. Now, the upcoming 2026 quota is well over 1 million lbs. Horseshoes crabs are a healthy resource in the State of Massachusetts, opportunities for commercial fishermen should be increasing or at the very least remain status quota. The constant outside pressure from Conservation groups whom only will be satisfied with a net-zero harvest level of horseshoe crabs is insulting to the Fishing Industry, the established Science and the Management efforts provided from the Division of Marine Fisheries.
Thank you,
Tom Luce

Horseshoe Crab Letter

Dear Drirector McKiernan,

My name is Jake Angelo and I am a commercial fisherman and wholesaler in the town of Barnstable. I would like to first say congratulations to the DMF for creating a sustainable horseshoe crab harvest back in 2010 with the lunar calendar closures. HSC populations have been increasing since then.

Despite this great success, year after year, the beach pickers and conch fishermen are forced back here to defend their right to harvest a sustainably managed species. Two years ago 60,000* crabs were reallocated to the biomedical sector, and last year the historically successful lunar calendar closures were replaced with an all out spring closure. The impact on these two changes is yet to be seen but considering prior data already showed increasing populations, further reducing our bait quota feels unjustified.

The DMF has no ability to restrict HSC sales to only Massachusetts fishermen. If the 100,000 crabs is based on the estimated crabs use by Massachusetts fishermen during a low effort year, then theoretically the other 40,000 will be sold out of state or saved for spring conch potting since you've eliminated our ability to harvest bait in the spring. If next year we only get to harvest 100,000 crabs, the number that reaches Massachusetts fishermen will be less than that creating a local shortage assuming efforts remain the same and worse if efforts increase. Effort and consequently landings of conch have been low for a few years following increased gage sizes and a crash in the market caused by recession and trade issues, however there has been an uptick in price this year which will likely entice more effort if the trend continues. That is unless our bait quota is whittled away and we don't have enough HSCs to fish with. How would you feel if there was an increase in effort and there was a shortage of crabs for your Massachusetts fishermen?

The vast majority that supports this proposal are extremely misinformed people who believe the horseshoe population is in jeopardy. The Mass Audubon Society posted a solicitation to submit a pre written public comment to their 61,000 Facebook followers with a few clicks of the mouse and this is how it starts. "Horseshoe crabs are iconic and valuable members of a biodiverse ecosystem. However, in Massachusetts, they're harvested for bait despite populations struggling to keep up." Mean while yesterday I saw the DMF's Facebook with 1/4 the followers post, "Good News, HSC Populations are increasing in Massachusetts!" Considering the Audubon's point and click public comments were enticed through blatant misinformation you should disregard those submissions.

I did some research on the Red Knot, the pinnacle of the Audubon's debate, and found that it

mainly feeds on HSC eggs in Delaware Bay not Massachusetts. In fact on the Mass Audubon website in the “find a bird” feature it reads,” The Red Knot is a very *uncommon spring* and locally abundant fall migrant in Massachusetts that has been proposed for listing as a federally Endangered species. The eastern North American population of this shorebird has shown a precipitous decline in recent years, attributable, in part, to the overfishing of horseshoe crabs, whose eggs constitute an essential portion of the Red Knot's diet during their *spring migratory stopover in Delaware Bay*.”

HSC populations have be increasing with leaps and bounds while Red Knots have not and the fact that Reds Knots are rarely seen in Massachusetts during the HSC spawn further shows the extent the Audubon will go to misinform the public and manipulate supporters.

On the National Audubon’s website bird guide under Red Knots diet reads,” Includes mollusks, insects, green vegetation, seeds. In migration and winter, feeds on small invertebrates that live in mud of intertidal zone, *especially* small mollusks, also marine worms, crustaceans. On breeding grounds, feeds mostly on insects, especially flies. Also eats much plant material, especially early in breeding season (when insects may be scarce), including shoots, buds, leaves, and seeds.” I find it strange there is no mention of HSC eggs, and considering its migratory range and range in diet, I find it hard to believe harvesting from increasing horseshoe crab populations are the reason for their decline.

NOAA has denied the petition to include horseshoe crabs to the endangered species list saying that,” We find that the claims presented by the petitions do not comprise substantial scientific or commercial information indicating inadequacies of existing regulatory mechanisms such that a reasonable person conducting an impartial scientific review would conclude that listing may be warranted.” These Audubon people are certainly not reasonable.

If I had a dollar for every, “I saw more HSC when I was a kid,” id be a rich man. The reality is that these individuals are experiencing the Mandela effect. They are all folks in their retirement who likely don’t get out on the water as much as when they were kids because if they did they would see the same horseshoe crabs everywhere that the scientists and fishermen are observing. I’m 34 years old and been on the water my entire life, and I actually see wayyy more horseshoe crabs now than when I was a kid. Just look at all the shed pictures DMF posted online this past fall.

As far as the repeated claims that the conch fishery is over fished, that at one point may have been true but it is not true in 2026. Your trawl surveys are not capable of adequately sampling a nocturnal, subterranean species during the day and since “DMF can’t justify funding a proper conch pot population survey for a fishery only worth 1.5 million dollars.” You have classified them over fished which has been used as ammunition against us.

In your letter to the Marine Fisheries Advisory Commission in November regarding the bills at the state house to outlaw horseshoe crab harvest you said,” Banning bait harvest will have significant direct and indirect impacts to the Commonwealth’s seafood industry. Although HSCs are not consumed by the public, their harvest and sale as bait are an important component to certain sectors of the commercial fishing economy. The cumulative impacts might be deleterious to the commercial fishing and seafood dealer sector, particularly along Cape Cod and the South Coast where most of the affected fisheries and processing activities occur, and negative impacts food production and seafood availability in the Commonwealth.

You and your staff know that the horseshoe crab bait fishery is a key fishery in our state waters that supports not just the fishermen but a whole chain of dealers, processors, all the way to the end consumers. You folks also know with almost certainty that maintaining a 140,000 crab quota will not have adverse impacts on the population. This is 3 years in a row you have made a proposal to chip away our fishery. Reducing our quota based on your estimated HSC consumption from a low effort year with out ensuring the crabs go to Massachusetts fishermen in my opinion is inconsiderate management. Like always, surplus crabs will find a home out of state, and if our effort increases we have the wiggle room at 140,000 crabs to accommodate that. You should be proud that Massachusetts has such a sustainable fishery that we can help neighboring states that fell victim to the Audubon Society war machine. Im sure you are as sick and tired of defending a sustainable harvest as much as I am, and I believe a lot of your motivation for this proposal is to appease the bird people so please stand behind the fishermen, and the data, and don't reallocate any more of our bait quota away. In fact now that I think about it please roll back the spring pick!

In response to possible possession limit reduction of the biomedical crab fishery.
I would like to share my thoughts and experiences

We have achieved zero mortality in the biomedical crab harvest aboard our vessel.
This success could not have been achieved if this was not a directed fishery for biomedical horseshoe crabs.

We've taken many steps to modify our fishing style to accomplish zero mortality verse Summer flounder techniques
We have modified our sweeps and cod ends, bottom tow time duration. Avoiding Shell gravel bottom which would lead to bleeding crabs or mortality.
We have two large horseshoe crab holding tanks 1000 gallons each, with high volume water flow for stabilizing the crabs

I believe reducing the biomedical possession limit would result in a summer flounder directed fishery with a by-catch of biomedical crabs
I don't know if the same caution will be given to the well-being of the horseshoe crabs, as the main focus will be on higher Summer Flounder, catch rates.

The laboratories require a steady supply of crabs, without a biomedical directed fishery the relationship dynamic will change,
there will be instability when there are a greater opportunities perhaps in the squid fishery, Whiting fishery, scallop fishery, etc.
vessels will come and go. We have seen this over the years.

Thank you for your time

Phillip Michaud jr

As a participant in the Horseshoe crab fishery in the state waters of Massachusetts, mainly in the Nantucket Sound area, I support the DMF proposal for the upcoming 2026 season.

We work consistently to ensure best handling practices are followed and refined if needed, with the ultimate goal being the lowest achievable mortality rate.

Additionally, we have taken both DMF scientists and observers whenever asked throughout the season, and have consistently demonstrated to both how low that rate is.

The Biomedical hsc fishery is one of the most sustainable i have participated in during my career, which is now spanning 30 years and many different mobile gear fisheries.

The health of the resource is excellent and is verified by science that includes both beach surveys as well as Massachusetts Division of Marine Fisheries trawl surveys.

Dear Massachusetts Division of Marine Fisheries,

These form letters are an embarassing pile of deliberate misinformation and in many cases lies.
The poor souls who sign them are victims of a deliberate attempt to mis-inform the general public, and put word in the mouths of people who dont know better.

They contain incorrect information and should be discarded or used to line a bird cage, or cat litter box. They have no value or use in intellegent discussion or debate.
They should all be treated like the garbage they are.
The hardworking people of Massachusetts deserve better than this.

Dan

Just saw your Facebook post about the meeting coming up tomorrow.
Ironically, I will be busy meeting with some colleagues to talk about a Horseshoe crab paper we are writing, based on volunteer surveys of horseshoe crab spawning in the Great Bay Estuary, NH.

Hopefully you are aware of some of my work with horseshoe crabs and bleeding, etc. If not, I can send you publications.

Bottom line:

If you treat them right, mortality can be lower than 20-30%.
For example, you can feed them before or after bleeding them. This is a big help.
Those females that do survive being bled will take about 2-4 weeks to recover and will only spawn half as much as normal females.

Most importantly, don't focus on the larger females and do not harvest them during their spawning season in May and June.

Subject: Proposed Reduction in the Horsehoe Crab Bait Fishery
Date: Friday, February 27, 2026 12:33:00 PM

CAUTION: This email originated from a sender outside of the Commonwealth of Massachusetts mail system. Do not click on links or open attachments unless you recognize the sender and know the content is safe.

Good Afternoon, I am writing to weigh in on the proposed reduction for the Horseshoe crab bait fishery in Massachusetts on behalf of the Massachusetts Conch Association. The Association is against any reduction in the current horseshoe crab bait fishery. A couple of years ago there were new rules enacted that basically stopped the beach harvesting of horseshoe crabs. This measure has helped increase the population of horseshoe crabs in the state. There is much science to back up this fact. Horseshoe crab is a necessary bait for conch fishermen. There is no substitute for this crab for bait. Currently most conch fishermen mix horseshoe crab in with other items to conserve on the use of the crab. Many states have either outright banned or severely reduced the harvest of horseshoe crabs. Many of the other states do not have enough supply for their own fishermen. Once the bait fishery is reduced it will never be increased again and this along with the reasons above are why the association is against any reduction in quota for the horseshoe crab bait fishery. Massachusetts needs to preserve and protect the bait supply from state waters for our own fishermen. If the state of Massachusetts will not support their own fishermen and vital shoreside businesses who will?

Director Dan McKiernan
MA Division of Marine Fisheries

Re: Proposed amendments to Division of Marine Fisheries regulations

Dear Director McKiernan,

On behalf of the Cape Cod Commercial Fishermen's Alliance, I write in opposition to the proposed reduction in the Horseshoe crab bait quota from 140,000 crabs to 100,000 crabs and the reallocation of these 40,000 crabs to the biomedical sector.

Our organization represents small-boat, community-based fishermen across Cape Cod who depend on responsibly managed local fisheries and access to sustainable bait sources. Our members are deeply committed to sustainable fishing practices, local stewardship, and science-based management of the Commonwealth's marine resources. The limited, highly regulated harvest of horseshoe crabs for bait in Massachusetts is a model for sustainable management that balances ecological protection with the economic realities of coastal communities.

The MA Division of Marine Fisheries already maintains comprehensive protections for horseshoe crabs that far exceed management measures in most neighboring states. Commercial harvesters must comply with:

- **Complete harvest closures during spawning periods** tied to the lunar cycle, ensuring crabs are protected during peak reproductive periods (April 15-June 7) in all Massachusetts waters;
- **Prohibition of harvest of horseshoe crabs** within the boundaries of the Cape Cod National Seashore and the Monomoy National Wildlife Refuge
- **Prohibition within the waters of Pleasant Bay** for bait fishery, implemented in 2006 and adopted permanently in 2007.
- **Strict permitting, reporting, and trip limits** (300 horseshoe crabs per trip limit for participants in the limited access bait fishery),enforced by the Division of Marine Fisheries (DMF) ensuring DMF has real-time monitoring of harvest activity

Starting in 2024, spawning horseshoe crabs received the added protection of a continuous 7 ½ week no-harvest closure from mid-April through June 7. This new rule replaced the state's 5-day "lunar closures" that surrounded each new and full moon in the spring which began in 2010. This new protection enhanced conservation by maximizing the spawning potential of the local populations. Based on data collected from MA Division of Marine Fisheries that described the timing of spawning activity, this closure time period will protect about 90% of spawning crabs, allowing them to deposit eggs on Massachusetts beaches undisturbed.

In Massachusetts, horseshoe crab populations appear to be increasing in recent years (MA DMF). The most recent stock assessments for Horseshoe crabs (2019 and 2024) showed abundance in Massachusetts has

BOARD OF DIRECTORS Andrew Baler • Richard Banks • Charles Borkoski • Greg Connors • Beau Gribbin
Eric Hesse • Barry LaBar • Sam Linnell • Bradley Louw • Kurt Martin • Jesse Rose • Brian Sherin

1566 Main Street, Chatham, MA 02633 (508) 945-2432 info@capecodfishermen.org www.capecodfishermen.org

been increasing since horseshoe crab management started in 1998, citing data from MA DMF's semi-annual trawl surveys. The MA Division of Marine Fisheries recently shared via social media that 2025 was a great year for horseshoe crabs in Massachusetts. They state: "Last year, we saw record numbers of female crabs in the spring trawl survey south of Cape Cod, the seine survey had its 3rd best year (behind 1988 and 2023), and 90% of the spawning beach surveys are showing increasing trends over the last ten years. In fact, over the past 10 to 15 years, we have seen positive trends in abundance across all three surveys."

Despite the increase in horseshoe crab populations, MA DMF has continued to manage this species conservatively with precautionary management and rigorous oversight. The bait fishery is subject to an annual quota. The quota was first set by Addendum I to the ASMFC Fishery Management Plan (2000) at 339,337 horseshoe crabs annually. In 2008, the MA Division of Marine Fisheries with the approval of the Marine Fisheries Advisory Commission instituted new regulations for the harvest of bait crabs, including reduction in annual quota from 330,337 to 165,000, and a reduction in daily limit from 1,000 to 400 crabs. In 2023, the Marine Fisheries Advisory Commission (MFAC) voted unanimously in favor of adopting additional conservative measures by MA Division of Marine Fisheries that cut the states quota for the bait fishery from 165,000 to 140,000 making it far below the state's 330,377 crab allowance in the Atlantic States Marine Fisheries Commission's interstate management plan (ASMFC 2024). These science-based measures are conservative and ensure that the Commonwealth's horseshoe crab population remains healthy while allowing a small number of horseshoe crab harvesters to continue a traditional bait harvest critical to local conch fisheries.

Currently there are 32 active horseshoe crab bait endorsement holders across Massachusetts (13 using hand gear, and 19 using mobile gear (Data sources: MATL Reports, NMFS VTRs). From 2022 to 2024, the top ten Massachusetts fishing ports with horseshoe crab bait landings, in order, were Chatham, Hyannis, Orleans, Harwich Port, Eastham, Woods Hole, Barnstable, Mashpee, Wellfleet, and Plymouth (Sources: MA Commercial Catch Reports, NMFS VTRs). The revenues from horseshoe crab landings contribute substantially to the profitability of these commercial fishing businesses, and for some mobile gear fishermen, it represents the second most valuable species retained. In 2024, dealers reported the bait fishery took 139,970 horseshoe crabs, about 99% of the annual 140,000 crab quota. Bait fishermen are required to sell their catch to authorized dealers, and the bait dealers re-sell these horseshoe crabs to supply the state's conch pot fishermen. Additionally, some horseshoe crabs are exported to other states where there is a demand for this bait. With this proposal, to reallocate 40,000 crabs to the biomedical sector, there are equity concerns in terms of a reduction to the bait sector, but also in terms of bait quota not remaining in Massachusetts if exported to other states, therefore limiting the supply available to conch fishermen here locally.

The limited horseshoe crab bait fishery is an important part of Cape's small-boat commercial fleet, supporting local conch and whelk fishermen who rely on horseshoe crab bait to maintain their livelihoods. In 2024, there were 127 conch pot endorsement permits issued, and 45 actively fished (MA Commercial Catch Reports and NMFS VTRS). The whelk fishery supports active commercial harvesters, many based in Cape Cod's small ports. The highest ports with conch landings were Martha's Vineyard (35.8%), Harwich Port (12.0%), and Chatham (11.9%). Horseshoe crabs are the primary bait for the conch pot fishery. Reduction to the bait harvest quota, also impacts the state's conch pot fishery because they would see a reduction in access to their primary bait source. Losing access to local horseshoe crabs will decrease the profitability of this fishery and force fishermen to use less productive bait at a time when this fishery is already dealing with economic factors impacting domestic and international market demand.

Reallocation horseshoe crab quota to the biomedical field would unnecessarily penalize compliant harvesters who follow the rules and operate under strict state regulations to ensure the sustainability of the resource. It would also increase dependence on imported or synthetic bait, raising costs for local fishermen and shifting ecological pressure to other regions where management standards may not be as robust. Trials testing effectiveness of alternative baits to horseshoe crab for whelk fisheries have been previously conducted and harvesters reported poor results (2017 Horseshoe Crab Technical Committee Report).

We urge you to maintain the quotas, which already provides strong conservation measures and protection, rather than reducing this well-managed local bait fishery. A reallocation of horseshoe crab quota to the

biomedical sector would have significant economic consequences for these fishermen and their communities while doing little to improve conservation outcomes beyond what existing protections already achieved through MA Division of Marine Fisheries. The best available science, supported by state and federal horseshoe crab biologists, demonstrates that horseshoe crab populations in Massachusetts are increasing in abundance. This is a direct result of MA DMF and ASMFC managing the species conservatively and with rigorous oversight.

Thank you for your attention to this issue and for your ongoing support of policies that sustain both our marine resources and the fishing communities that depend on them.

Sincerely,

Aubrey Church

Re: Public Comment on Proposed Horseshoe Crab Quota Reallocation

Dear Members of the Marine Fisheries Advisory Commission:

On behalf of the Massachusetts Conch Association, I write to provide comments regarding the Division of Marine Fisheries' proposal to reduce the bait horseshoe crab quota from 140,000 crabs to 100,000 crabs and reallocate the remaining quota to the biomedical sector.

The Massachusetts conch (whelk) fishery is a vital component of the Commonwealth's maritime economy. It is composed primarily of small, family-run businesses that supply sustainable, locally harvested seafood to domestic and international markets. Approximately 150 Massachusetts permit holders depend on reliable access to horseshoe crab bait to maintain their operations. The commercial bait industry also supports the eel fishery, another important sector of the Commonwealth's coastal economy.

While we appreciate the Division's efforts to align quota management with evolving market conditions, the proposed reallocation raises significant concerns for fishermen whose livelihoods depend on this resource.

1. The Proposal Does Not Adequately Reflect the Needs of the Conch Fishery

The Division's proposal assumes that bait demand for the conch fishery will remain between approximately 75,000 and 90,000 crabs annually. While historical data may suggest reduced effort in recent years, quota decisions should not lock the fishery into a reduced baseline that may reflect temporary market conditions rather than long-term demand.

The conch fishery has historically experienced fluctuations tied to export markets, regulatory adjustments, and environmental conditions. Should market demand improve or effort rebound, a reduced bait quota could unnecessarily constrain fishermen and undermine the fishery's ability to recover. Maintaining sufficient quota flexibility is essential to allow the fishery to respond to changing economic conditions.

Equally important, there is currently no viable substitute for horseshoe crab bait in the conch fishery. Fishermen often combine horseshoe crab with other bait sources as part of regular

and sustainable fishing practices, but the horseshoe crab remains the essential component that makes the fishery economically viable.

2. Disproportionate Allocation to the Biomedical Sector Raises Equity Concerns

The proposed reallocation would significantly increase the biomedical quota while reducing the quota available for bait harvest. This shift effectively prioritizes the needs of a relatively small number of biomedical processors over the broader community of commercial fishermen who rely on horseshoe crabs as bait.

Although biomedical harvest is described as catch-and-release, available research suggests mortality rates of approximately 15–30 percent following the bleeding process, along with potential sublethal effects on reproduction and long-term survival. As a result, increasing biomedical access to horseshoe crabs does not necessarily produce the conservation benefits often assumed.

By contrast, the bait fishery operates under strict trip limits, quotas, and reporting requirements. Fishermen utilize the resource efficiently to support a domestic seafood industry that provides economic benefits across Massachusetts coastal communities.

3. Massachusetts Fishermen Have Limited Alternative Supply Options

Massachusetts fishermen rely almost entirely on horseshoe crabs harvested from state waters. Other states have imposed outright bans or severe harvest reductions, making it difficult or impossible to obtain horseshoe crabs from outside Massachusetts. As a result, reducing the Commonwealth's bait quota could effectively leave fishermen without any reliable alternative source of bait.

Once bait quotas are reduced, they are rarely restored. For many fishermen, this proposal therefore raises concern that a temporary shift in management could become a permanent constraint on the fishery.

4. The Proposal May Further Concentrate Access to the Fishery

Over the past decade, management changes have increasingly shifted participation in the horseshoe crab fishery toward larger mobile gear operations and entities with direct relationships to biomedical processors. Expanding the biomedical quota risks further concentrating access to the resource among a smaller number of participants while limiting opportunities for traditional bait harvesters.

Maintaining balanced access to horseshoe crab harvest is critical to ensuring that the economic benefits of this resource remain distributed throughout the Commonwealth's waterfront communities.

5. Adaptive Management Remains the Appropriate Framework

Massachusetts has long been a leader in science-based fisheries management. The Division of Marine Fisheries already possesses the regulatory tools necessary to manage horseshoe crab harvest through adaptive quota adjustments, trip limits, and seasonal controls.

Rather than implementing a significant structural shift in quota allocation, the Commission should consider whether other alternatives would better balance conservation goals with the needs of commercial fishermen.

Conclusion

The Massachusetts Conch Association supports responsible stewardship of the Commonwealth's marine resources and recognizes the importance of maintaining healthy horseshoe crab populations. However, the proposed quota reallocation risks undermining a long-standing commercial fishery that supports numerous small businesses and coastal communities.

For these reasons, we respectfully urge the Marine Fisheries Advisory Commission to reconsider the proposed quota reallocation or, at minimum, ensure that any changes preserve sufficient bait availability to support the continued viability of the Massachusetts conch fishery.

We appreciate the opportunity to provide these comments and look forward to continued collaboration with the Division and the Commission on responsible, science-based fisheries management.

Very Truly Yours,

Samuel P. Blatchley

ATTN: Dan McKiernan.
Suggestions:
Sea Bass regulatory changes:
Perhaps propose 6 days per week opening, beginning July 1. Instead of a 5-day. This will enable capitalizing on higher prices for Jumbo and Large sea bass as they are more prevalent earlier in the season. The previous few years, by September, Jumbo and Large sea bass begin migrating out of range, eventually leaving only medium sea bass left to harvest. And they are not worth much .75 cents-1.00$ per pound.
Also, a concerted effort to promote and market Black Sea Bass is desperately needed. Very rarely do you see Black Sea bass on local menus or fish markets. Frustratingly, the fishery is still heavily dependent on the Asian market.

Horseshoe Crab:
The most important issue is to protect horseshoe crab harvesting in the State of Massachusetts. Bill H.898 in the MA State Legislature wants to permanently ban Bait harvesting levels to zero. But not the biomedical? No horseshoe crabs-no Conch Pot Fishery. Using alternative baits would result in a minimum 50% catch rate loss, essentially eliminating any profit. And wiping out the fishery. The Horseshoe Crab assessment/recruitment in MA waters is healthy and has been quota managed since 1998. The Red Knot bird migration pattern does not coincide with the Massachusetts horseshoe crab spawning timeframe. And in fact, research shows they migrate Northwest from their Delaware Bay stop over area towards St. John's/Hudson Bay. Therefore, not a factor in MA waters-a main issue the environmental/conservation organizations always focus on. There is no justification to end the bait harvest, this bill should be easily voted down in favor of the fishermen.

In 2025, percentages for Bio/Bait harvesting was 60%-40% respectively. Changing the crab allotments for 2026 doesn't change the percentages. The poundage is only borrowed due to the current assessment of bait usage. It's hard to believe the Biomedical Industry willingly sacrificing their quota in the future for the bait market. Hence, the need to solidify quota percentages going forward.
The conch gauge increases is definitely the main reason for reduced effort, directly leading to less bait usage. But this can change in the near future-replenished conch due to the gauge size conservation measures. And especially if market conditions stabilize and improve.
Also, marketing and awareness for Channeled Whelk is a must. Another fishery unknown outside of niche ethnic markets. The Florida keys and South Florida is well known for having several conch dishes. Local Jamaicans and Caribbeans on Cape Cod adamantly praise our Conch as better than the Queen Conch. And yet, again, the Massachusetts Conch pot fishery is mainly dependent on the Asian markets.
Thanks for reading Dan.

CAUTION: This email originated from a sender outside of the Commonwealth of Massachusetts mail system. Do not click on links or open attachments unless you recognize the sender and know the content is safe.

Dear DMF,

I am writing to you in regards to the pending horseshoe crab harvest restrictions. After years of keeping a close eye on the horseshoe crab populations and the legislation around it, I would like to thank you for bringing their population back and protecting them. In the last decade they have been classified by the state as stable and improving. This has been done by your team of researchers and the regulations you have enforced. Congratulations on this achievement.

The Audubon society is pushing a different story. They are showing pictures of molted crabs saying they're being wiped out. They are begging the public to stop the bait fishery and demonizing our working waterfront and fishermen. They have been pushing a false narrative that horse shoe crabs are being depleted by the few fishermen who target them. It is not right or fair to fishermen and the people who depend on this fishery directly or indirectly for this non profit to continue to push this narrative. Clearly they are well established and have a larger support network than any group of fishermen. DMF went against the science when Audubon made a push to get ride of the "spring pick". This hurt small boat fisherman. As someone who make their living on the water, this also put a lot of uncertainty in my career. I do not have a horseshoe crab permit or a conch permit but it left me wondering, will groups like these always get their way when demonizing fisherman?

Moving 40,000 crabs from the bait fishery to the biomedical industry will once again hurt small boat fisheries and benefit draggers, they same way it did when the spring pick was eliminated.
DMF went against the science when getting rid of the spring pick, so this time around I ask that your team stays true to its own research to not only protect the small quota that is left, but also consider bringing back the spring pick.

Thank you,
Tyler Hagenstein
Channel Rock Oyster Company

Department of Marine Fisheries

Re: Opposing to the reduction of Horseshoe crab bait proposal

Good Morning:

My name is Henry Borges. I have been conching for over 25 years. I strongly oppose the reduction in the horseshoe crab bait proposal. As your department has reported there is an increase in the horseshoe crab numbers. Until scientific data shows a reduction in the horseshoe crab numbers the quota should stay the way it is presently.

I fully support Jake Angelo's comments at the zoom meeting on March 4, 2026. He researched many sources on horseshoe crab numbers and their effects on other species. There is no data to support a need for further reduction.

I feel cutting the quota will cause undue hardship to the conch and dragger fisheries.

Thank you for your consideration of my comment.

Regards,

HenryBorges
220 Bakerville Road
Dartmouth, MA 02748

March 5, 2026

Dear Director McKiernan,

My name is Rachel Lynn, and I am a resident of West Barnstable, Massachusetts. I come from a fishing family that holds a conch pot license, and I have been following the management of the horseshoe crab fishery closely for several years.

In 2023, I attended a meeting at the Division of Marine Fisheries office in New Bedford where the initial reduction in the bait quota, from 165,000 to 140,000, was discussed. During that meeting, staff presented data showing a steady increase in horseshoe crab populations since the implementation of the lunar closures in 2010.

After that meeting, and hearing opposition from fishermen, the bait fishery was reduced by 25,000 horseshoe crabs. Then, in 2024, the “spring” horseshoe crab fishery was closed. Both measures have had real impacts on fishermen, and the hand-picking fishery has faced practical extinction as a result (addressed in the 12/12/25 memorandum).

Given these recent changes, I do not see a clear justification for further reductions geared toward the bait fishery at this time. Two significant management measures have already been implemented in a relatively short period: a reduction and a significant closure. An additional reduction of 40,000 crabs from the bait fishery would have ripple effects across multiple fisheries and throughout the Massachusetts seafood supply chain.

Horseshoe crab bait is essential for the conch fishery, and there is currently no viable substitute. As a result, every reduction in the bait quota directly limits fishermen’s ability to harvest conch.

It is also important to be cautious when evaluating quota changes based on short-term fishing trends. In recent years, price suppression in the conch market has reduced fishing effort, which, in turn, has affected reported landings and participation. Fishermen must often be nimble and shift effort to other fisheries when market conditions are weak. However, reducing the bait quota based on these temporary economic trends could prevent the conch fishery from recovering and returning to historic fishing levels when markets improve. There needs to be adequate bait.

I respectfully urge the Division to consider the cumulative impacts of the recent management decisions, as well as the data demonstrating the effectiveness of existing conservation measures, before pursuing further reductions to the bait quota. Any consideration of reallocating quota toward biomedical purposes should account for these cumulative effects and the longstanding role that horseshoe crab bait has played in supporting fisheries that feed people.

Thank you for your time and consideration.

Sincerely,

Rachel Lynn

Attn: Director Daniel J. McKiernan

Subject: Public Comment on Proposed Horseshoe Crab Quota Transfer

Dear Director McKiernan,

Thank you for the opportunity to participate in public commentary. We respectfully submit the following comments regarding the Division's December 2025 proposal to transfer 40,000 horseshoe crabs from the bait quota to the biomedical quota, increasing the biomedical quota from 200,000 to 280,000 crabs annually.

Statement of Support for the Division's Proposal

Shellfish Broker LLC supports the Division's proposal, as presented at the December 2025 Marine Fisheries Advisory Commission meeting, to transfer 40,000 horseshoe crabs from the bait quota to the biomedical quota. This proposal reflects years of data and science-based management by the Division. Additionally, it represents a conservation-aligned approach to reducing overall horseshoe crab mortality while preserving the vital Rent-A-Crab program that services the important needs of the Massachusetts conch fishery.

The Massachusetts Division of Marine Fisheries has demonstrated a long-standing commitment to responsible stewardship of the Commonwealth's marine resources through rigorous monitoring, extensive field observation, and adaptive management grounded in science. With a staff of approximately 100, not including a fluctuating seasonal staff of approximately 25, the Division employs highly trained biologists, scientists, and fisheries managers who devote substantial effort and resources to ensuring that management decisions promote both conservation and sustainability and remain grounded in science.

Based on the Division's extensive monitoring programs, stock assessments, and operational oversight, this quota transfer represents a measured and appropriate adjustment that aligns quota allocation with observed patterns of utilization and

conservation objectives. Supporting this proposal will help ensure that a proportion of authorized harvest occurs within the biomedical category, where animals can be returned alive, thereby reducing overall mortality while also protecting the needs of the channeled whelk fishery.

For these reasons, we respectfully encourage the Marine Fisheries Advisory Commission to approve the Division's science grounded proposal as presented.

Because biomedical use allows for post-processing release and survival, maximizing access to biomedical quota prior to reliance on bait harvest helps reduce overall mortality. Ensuring that authorized biomedical quota can be fully utilized within established biomedical handling protocols helps ensure that the conservation objectives underlying this quota transfer are fully realized.

Our firm has consistently demonstrated the capacity to fully utilize its biomedical allocation and has historically met additional biomedical demand through lawful participation in the bait quota via the rent-a-crab program. This reflects the practical importance of ensuring that allocation structures support full and efficient utilization of authorized biomedical quota.

Ensuring that biomedical quota is structured in a manner that promotes full utilization within established biomedical handling protocols will help ensure that the intended conservation benefits of this quota transfer are fully achieved.

The Commonwealth of Massachusetts has demonstrated national leadership in the science-based stewardship of horseshoe crab resources. Supporting this proposal represents an important step in continuing that leadership and ensuring the long-term sustainability of this vital public trust resource for all stakeholders.

Thank you for your continued leadership and stewardship, and for the opportunity to provide these comments.

Respectfully submitted,

Shellfish Broker LLC

March 6, 2026

Massachusetts Division of Marine Fisheries

836 S. Rodney French Blvd.

New Bedford, MA 02744

Attn: Director Daniel J. McKiernan and Honorable Members of the Marine Fisheries Advisory Commission

Subject: Addendum Public Comment — Biomedical Horseshoe Crab Trip Limits

Dear Director McKiernan and Honorable Members of the Marine Fisheries Advisory Commission,

During the Division's recent public hearings regarding the proposed transfer of 40,000 horseshoe crabs from the bait quota to the biomedical quota, several commenters suggested that the current biomedical trip limit of 1,000 horseshoe crabs per day should be reduced to a level more closely aligned with the bait fishery trip limit of 300 crabs per day.

These suggestions were offered without supporting analysis, scientific justification, or operational explanation. For the benefit of the administrative record, and to assist the Commission in its deliberations, I respectfully submit the following clarifications.

First, the subject of biomedical trip limits is not part of the Division's current proposal.

The December 2025 memorandum and accompanying regulatory materials address only the reallocation of quota between the bait and biomedical sectors. No changes to biomedical trip limits were proposed, analyzed, or discussed in the Division's regulatory presentation.

Accordingly, altering biomedical trip limits within the context of this rulemaking would fall outside the scope of the proposal currently before the Commission.

Second, the current biomedical trip limit framework has been in place for many years and predates our firm's participation in the biomedical horseshoe crab industry. It is the framework set out by the DMF that we have adhered to.

The operational structure of the biomedical fishery—including vessel handling procedures, transport logistics, holding protocols, and compliance measures—has evolved over time within the context of this established regulatory model.

Our company's **Standard Operating Procedures,** under regulatory oversight, have been developed and refined over the last five years to ensure full compliance with the Best Management Practices established through the Atlantic States Marine Fisheries Commission and implemented through Massachusetts regulation in 2023. These practices represent the product of extensive collaboration among regulators, scientists, and industry participants with the shared conservation objective of minimizing horseshoe crab mortality associated with biomedical use.

Equally important, the extensive scientific monitoring conducted by the Massachusetts Division of Marine Fisheries, over years—including at-sea observations, dealer monitoring, and biomedical sampling—has been conducted within the framework of the current biomedical trip limit model. The resulting dataset, which has been presented annually during the Massachusetts Horseshoe Crab Science Meeting, reflects the performance of the fishery under the existing regulatory structure.

Introducing a substantial change to the biomedical trip limit would therefore introduce a new operational variable into a fishery management model that has been the basis for years of monitoring and scientific analysis. Such a change would complicate the interpretation of historical data and could make direct comparisons with past mortality and survivability observations far more difficult.

Most importantly, biomedical collection and handling procedures have been refined over many years with the explicit objective of minimizing stress and mortality among horseshoe crabs collected for biomedical purposes. These procedures—including vessel operations, transport timing, and holding practices—are designed around the operational and trip limit framework under which the fishery has functioned.

Substantial changes to that framework, including trip limit reductions, could alter operational patterns in ways that increase handling time, transportation complexity, or other stressors affecting horseshoe crab survivability. For this reason, any proposal to modify biomedical trip limits would warrant careful scientific evaluation before implementation.

Given that the Division's stated objective in the current proposal is to reduce overall horseshoe crab mortality by shifting allocation from the bait sector to the biomedical

sector, introducing unrelated regulatory changes to the biomedical fishery at this time could undermine the stability of the management framework that has produced the Division's current body of scientific observations.

The Massachusetts Division of Marine Fisheries has developed one of the most carefully monitored and scientifically managed horseshoe crab programs on the Atlantic coast. Maintaining stability in operational regulations that are not under consideration in the present proposal will help ensure that the Division's monitoring programs remain meaningful and that the conservation objectives underlying the current quota transfer are fully realized.

For these reasons, I respectfully encourage the Commission to limit its deliberations to the proposal currently before it and to maintain the existing biomedical trip limit structure unless and until a separate, science-based review of this issue is undertaken.

Thank you for your continued stewardship of the Commonwealth's marine resources and for your careful consideration of these comments.

Respectfully submitted,

Jamie Bassett

Re: Proposal on Horseshoe Crab Quota Management

Dear Director McKiernan,

Charles River Laboratories International, Inc. appreciates the opportunity to provide comments on the Massachusetts Division of Marine Fisheries' (MA DMF) proposal regarding horseshoe crab quota management. Your consideration of our commentary is appreciated.

Charles River Laboratories is headquartered in Massachusetts and employs more than 2,100 people across eleven sites throughout the Commonwealth and 19,000 globally. From pre-clinical trials to manufacturing, we are in the business of protecting human health. One of our major products contains Limulus Amebocyte Lysate ("LAL"), the most sensitive and accurate material to detect endotoxin contamination in many human healthcare products. LAL has a long history of criticality to the biopharmaceutical supply chain as a required step for the safe manufacture and distribution of every implantable medical device and injectable pharmaceutical.

LAL is currently the FDA-approved gold standard product for endotoxin contamination testing in biopharmaceutical products, and Charles River's LAL products are used to ensure the safety of approximately 50% of the global supply of implantable and injectable products. Without this vital and proven substance, the biopharmaceutical supply chain is susceptible to contamination and patient safety would be at risk. LAL is an extract from the blood of the horseshoe crab. LAL is collected in a highly controlled and monitored process in which the crabs are temporarily and humanely removed from and returned to their habitats.

Charles River Labs is proud to offer Trillium Recombinant Cascade Reagents (synthetic products that do not require extracts of horseshoe crab blood) in both vial and cartridge formats. USP Chapter <86> has created the opportunity for our customers to validate compatible new products and revalidate existing compatible product testing with recombinant endotoxin reagents. In practice, however, validation can be time-consuming and costly, and recombinant reagents are not compatible with all products or processes. Accordingly, there remains an urgent need for continued access to LAL derived from wild horseshoe crabs to meet current patient and public health needs.

Charles River Labs stands with MA DMF to protect the sustainable usage of horseshoe crab populations in Massachusetts. As a result, we are in support of the proposed amendments to 322 CMR 6.34 to (a) reduce the annual horseshoe crab bait quota from 140,000 to 100,000 crabs, and (b) reallocate these

40,000 crabs to the biomedical quota at a 1:2 ratio, increasing the biomedical limit from 200,000 to 280,000 crabs.

The proposed reallocation to the biomedical sector at a 1:2 ratio is materially more conservative than the empirical mortality would justify and will, in aggregate, decrease total mortality while meeting current biomedical demand. Because biomedical crabs are returned to sea—rather than harvested—mortality is significantly lower. Allowing 40,000 bait crabs to be reallocated as 80,000 biomedical crabs acknowledges this difference and results in a net reduction in overall horseshoe crab mortality.

To realize the intended benefits—conservation, public-health assurance, and economic stability—the quotas should be managed to enable full and efficient utilization. Full utilization ensures the biomedical sector can reliably perform required bacterial endotoxin testing, the bait sector retains a viable and predictable operating environment, and managers receive complete effort and catch-and-release data to support adaptive, evidence-based decision-making. Targeting full and efficient quota usage will improve transparency, year-over-year comparability, and future stock assessments.

The proposed amendments to 322 CMR 6.34 are consistent with sound, science-based fisheries management. They reduce overall mortality, protect public health through reliable LAL availability, sustain Massachusetts' economic activity and working waterfronts, and enhance long-term stock resilience. For these reasons, Charles River Laboratories respectfully urge adoption of the quota adjustments and management for full, efficient utilization.

Charles River remains committed to responsible stewardship of horseshoe crab populations and continued collaboration with regulators, fishermen, and scientific partners. We thank the MA DMF and MA Marine Fisheries Advisory Commission for their consideration of these points and their support and stewardship of this vital and life-saving population and fishery.

Sincerely,

Nora Blair, Associate Director of Endosafe Testing and Natural Resource Conservation, Charles River Labs

Mar 5, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mr. Brennan Foley

Mar 4, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

I was part of the advocacy campaign by Mass Audubon in 2024 to help pass 322 CMR 6.34 to support regulations to protect horseshoe crabs during the spawning season. While that was a good first step, reducing the bait harvest quota will be another important step toward protecting these ancient and environmentally important creatures.

As humans, I feel it is important for us to protect the natural world, including animals, from destruction. As some people say, there is no Planet B. The horseshoe crab as a species is more than 300 million years old. It would be a shame for their numbers to continue to decrease, especially since their eggs provide food for the endangered red knots as they migrate from the southern tip of South America to the Arctic.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. Jac-Lynn Stark

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Shorebirds are among the most rapidly declining group of birds. Horseshoe crab eggs are a crucial resource for these and other global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden.

I have been watching horseshoes crabs come up on the beaches of Wellfleet to lay their eggs since the early 1970s, and my husband's experience goes back to the 1950s. The decline in their numbers has been obvious and disheartening. I would much prefer to see the bait harvest eliminated all together, but am very pleased to support this proposed reduction.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mr. Paul Toomey

Mar 1, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Feb 28, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds and who knows what else; Shorebird populations are crashing, apparently (in most species) because of declines of key foods at migration stopover places.

But more importantly, any harvest that targets breeding populations of any animal is sure to descimate its populations. Resource agencies like DNR surely know this, so I applaud reducing the lethal bait harvest of breeding Limulus.

Thank you for "walking the tightrope" and doing the right thing.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mr. Brian Harrington

Feb 28, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

On a more personal note Director, I have championed the horseshoe crab's unique life to our ecosystem by bringing this amazing "living fossil" to my urban middle school classroom, during ocean adventures, and within an illustrated field notes section. In my research I have learned that there are synthetic alternatives of their blood. Stopping this biomedical harvest through these synthetic alternatives is best practice. For more information, I would encourage you to review them at https://urldefense.com/v3/__https://www.horseshoes.org__;!!CPANwP4y!SB85IgpW25PbUGNwcXN45jEj4qBQylPuVKQiyfUUbieibKz5f4GWInYiDF5cbcGDQ0osmh8z34MS4F8h4FesAdt4bQ$. and locally at https://urldefense.com/v3/__http://www.necwa.org__;!!CPANwP4y!SB85IgpW25PbUGNwcXN45jEj4qBQylPuVKQiyfUUbieibKz5f4GWInYiDF5cbcGDQ0osmh8z34MS4F8h4FdpfomQwg$.

Thank you for adopting the synthetic alternatives and not directly harvesting the blood of horseshoe crabs

Thank you,
Sincerely,
Laurie Grandmont

Feb 28, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

With both pharmaceutical regulators and the biomedical industry moving toward synthetic alternatives, it's time to decrease--not increase--the number of crabs subjected to this inhumane process. Fifteen to 30 percent of horseshoe crabs do not survive this ordeal, and those who do may have compromised welfare for weeks afterward.

A synthetic, animal-free alternative using recombinant factor C (rFC) reagents has been available commercially since 2004, and was recently officially endorsed by the US Pharmacopeia, which sets federal quality standards for pharmaceuticals. Some major biomedical companies, such as Eli Lilly and GSK, have already made substantial progress in implementing synthetic alternatives for their endotoxin testing, while others are at varying points in the transition. To increase the biomedical harvest quota now would be to de-incentivize the transition to humane alternatives.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Feb 28, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

I have fond memories of seeing horseshoe crabs on the beach as a kid. They've become an increasingly rare sighting these days. Please act to protect this iconic species.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. Jessica Bryant

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Why wouldn't we want to try to protect the coastal environment? So much depends on the coast here in Massachusetts...the birdlife, the sea life as well as all the enjoyment we get from the beaches and the shore birds. In recent history we have destroyed so much of what keeps us part of the earthly community. It's shameful. Please stop the practice of killing what has made us special.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mrs. Linda Cornell

Feb 27, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crabs are an ancient and remarkable animal. They survived the rise and fall of dinosaurs and all the natural phenomena since then. While their unique blood has literally saved human lives (via its use in biomedicine) and is still needed for medical applications, there is no reason for horseshoe crabs to be done in by humans. We don't need to harvest them as bait. That's a waste. Please support the proposal that would decrease the use of this irreplaceable natural resource for bait.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Miss Kathleen Florentine

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.
I grew up on the bay in Brewster and have watched the dramatic decline in numbers from the 1960's till now, and, disturbingly, a significant decline in just the past 3-5 years.
There is no reason to harvest any horshoecrabs and I support any efforts to halt this short-sighted and selfish practice.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Feb 27, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Killing horseshoe crabs for bait is senseless and short-sighted, and it seems crazy to me that their very existence is threatened by such behavior. Especially when we--or you, as the group responsible for this decision--have such power to reverse the species' decline. Please vote yes to protect horseshoe crabs!
Thank you.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mrs. Eliza Anderson

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

We in New England are fortunate to have the horseshoe crab, this rare prehistoric species that continues to play a significant role in the coastal ecosystem. I have special memories of finding them while vacationing on Cape Cod, and my grandchildren have shared that wonder. To use them as bait and risk losing this species is foolhardy. We must end that practice and celebrate this rare and unusual species.
Christie Higginbottom

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Considering how essential the use of horseshoe crabs are to the biotech and pharmaceutical industries, it's ridiculous that this species is still fished for bait when so many other options for bait are available. The bait fishing should be completely phased out as long as there is no synthetic source of the endotoxin test.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Feb 26, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. Kalei Ensminger

But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

When I was a child growing up in Mattapoisett I remember the beach would sometimes be covered with living horseshoe crabs. Many decades later, I am lucky to be able to walk at Crane Beach in Ipswich in the early mornings. Now there are just a few horseshoe crab shells that wash up now and then. I read a great book about them "The Narrow Edge" by Deborah Cramer which points out how ancient they are, and what an important role they play in in the life cycle of migratory birds. It is a waste to use them as bait, and there are now alternatives to biomedical uses. I support any measure that reduces the needless killing of this important species.

Thanks for you time,
Gwen Holt

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.
Horseshoe crabs have contributed to human medicine in 2 ways: (1) Dr. H.K. Hartline studied a large nerve cell in the eye of these crabs and identified "lateral inhibition" in neuronal activity which was new to science (Nobel 1967). This information has contributed to better understanding of the human nervous system. (2) horseshoe crab blood is used to conduct specific useful blood tests, but today a synthetic substitute blood is also available. No reason to risk losing this species because of continued blood draws. It would be tragic if we lost the species because we did not stop blood draws and transitioned to using already available blood assays.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

I was involved in monitoring horseshoe crabs in Pleasant Bay in Chatham. There were significant declines in the population. I also live near the Great Sippewissett Marsh and Woodneck Marsh/Beach in Falmouth during the summer. These areas are critical spawning areas for horseshoe crabs and bird populations. Humans have been selfish in over harvesting simply to harvest whelks that are then sold overseas. Horseshoe crab blood was a key medical advance but scientists have been able to replicate their blood so the horseshoe crab bleeding should be banned. We are destroying what is around us all for the sake of financial gain with disregard for nature that is critical for creature that we share this planet with.
I support this these changes for harvesting regulations.

Feb 26, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. Theodora Martin

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Dear Director McKiernan,
Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds including the Red Knot have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds, while I have enjoyed observing them for many years, in Massachusetts and other regions along their epic global migratory journeys. It would be devastating to think that we would not act to maintain the ability of residents of Massachusetts to enjoy these and several other shore bird species.
While the new proposed rule is a step in the right direction and therefore urgently needed as the migration will soon begin again, I urge you to also consider banning their harvest for any purpose until numbers are restored and stable. At such point the active monitoring and management of the horseshoe population might allow limited harvest for legitimate purposes where alternatives are not available. Harvests for biomedical research are no longer valid as synthetic blood products are now widely available.
Many thanks taking the immediate necessary action to protect the horseshoe crab and all those other species that depend upon it, and on behalf of those who love nature and birds.
Mark Hibberd MD PhD

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Aside from all these great environmental reasons for protecting these creatures, they are truly amazing to see on our state's beaches. For many summers, when my son was young, we spent a week at the Cape and admired and wondered at the many shed shells we found on the sand. They were often incorporated into our sand castles and found art projects. Horseshoe crabs are very old inhabitants of Massachusetts, they deserve protection.
Thank you,
D. Diemente

Feb 26, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. Judith Taylor

Feb 26, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Horseshoe crabs and the eggs they hold are not an infinite resource. The crabs are harvested as if they were plentiful but they just aren't. The shorebirds soming up our coast to the artic have nowhere else to stop for food besides our shores. They have evolved to rely on the Horseshoe crab eggs as a food source. They time their migration to match the availability of the Horseshoe crab eggs. We are responsibile for the damage we do. We must treat the resource as finite and manage it well for the sake of all, birds and people.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mr. John Edmondson

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. Given the ecological, cultural, and economic importance of horseshoe crabs, the unnecessary harvest of these animals to be used as bait should be phased out completely. In addition, horseshoe crab eggs are a crucial resource for global migratory birds and rare shorebirds.

I have fond personal memories of encountering these distinctive creatures as a child on the beaches of the North Shore, experiences that opened a door to nature appreciation. It turns out they are a linchpin for biodiverse marine habitats we all rely on.

Yours sincerely,

Phoebe McKinnell

But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

These amazing animals deserve to survive as a species, and the current rate of human killing is far too high to allow that. Especially given the climate-change-fueled transformation happening to waterfront areas - where the horseshoe crabs must come to reproduce - we must act with caution and be especially good stewards. Please vote for good stewardship of these remarkable animals.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Feb 26, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

I hope that this proposed measured approach and the reduction of the use of horseshoe crabs for bait will be seen as common-sense preservation tactics. We need to take care of our environment protecting vulnerable populations and striving for a balance in what we take from nature. Horseshoe crabs are a remarkable species, and we need to find ways to keep them on this planet.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Hello! I live on Pleasant Bay in Orleans, MA, and I am lucky enough to see firsthand how important Horseshoe crabs are. The Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds. Personally, the number of Horseshoe crabs I see while walking Pleasant Pay seems to be declining - they do not seem to be a numerous as they once were. As a keystone species in our environment, you are also helping so many other species as well. This species has been on the earth for hundreds of millions of years - it's so intertwined with our coastal ecosystem.
Please proceed with adopting these changes in harvesting regulations.
Sincerely, Sharon Gill, Orleans, MA

Feb 26, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

I live on the coast. We used to see our shoe crabs, and now they are exceedingly rare.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. Laura Hallowell

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

As a child in the 1970's I ran around the Cape Cod salt marshes and collected horseshoe crab shells. They're such an interesting creature and so important to the salt marsh ecosystem.

When I ran around the Cape Cod salt marshes with my children I saw the sharp decline of the horseshoe crabs.

When I run around the Cape Cod salt marsh with my grandson the horseshoe crab shells are very rare.

The bait and biomedical harvests have devistated the horseshoe crab population on Cape Cod and it has ramifications across the entire salt marsh ecosystem. We need to protect these creatures.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.
I care very deeply about preserving our natural resources and fragile environment. Horseshoe crabs are extraordinary creatures in and of themselves, well worthy of our admiration protection. Their importance in the ecological food chain cannot be underestimated, and - given the already intense stresses on their population - their use by humans should be limited to cancer research on their blood. To use them as bait is antiquated and ridiculous, when there are multiple equivalent - or superior! - choices.
I strongly urge you to support the DMF's proposal.
Thank you in advance for your careful consideration.

Feb 26, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

So I agree with the proposal to limit the crabs from fishermen's bait. However, the biomedical community should not be allowed to harvest them either. It has been proven that the crabs do not survive well after "bleeding" , nor do they reproduce well, so basically they are useless after the 'bleeding" even though they are released back into the wild.

Both the fishermen and the bio labs use must stop.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. Elizabeth Lehman

Feb 26, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

As someone who studied and worked with horseshoe crabs during undergrad, I both understand their unique qualities both as a fascinating animal and the research contributions for their blood. While there is a 100% mortality for bait, obviously, it is somewhat understood that it is very likely the mortality is much higher than the direct 15% in lab once they are returned to the ocean. More research (on them, not with them!) needs to be done before anything is further refined but this would be a good start. With bait catches are often underreported and this acting as more of a deterrent, and hopefully overall blood collection REAL mortally rates being 50%, this would still be essentially at least a break even number for now, and start wheels turning for more sustainable and hopefully ethical processes for biomedical research going forward.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Dear Marine Fisheries Advisory Council,

I am writing to ask you to please adopt DMF's changes to protect Horseshoe Crabs. These changes are important.

When I was growing up in Quincy, MA I used to see so many horseshoe crabs on Wollaston Beach. I have fond memories of picking up their tails to turn the over so they could go out with the tide. I see them no longer and, for many years now, they have been absent. It is sad they are no longer as strong and vibrant as they were. As you likely know, when one species fails, others do.

Please do what you can to protect them. Thank you.

Sincerely,

Feb 26, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds. When I moved here from Michigan 60 years ago, I had never seen or heard of horseshoe crabs. I have been fascinated with them ever since that first encounter. I was heartbroken to learn that they are blead to do lab tests and used for bait. In this day and age when we have so many medical advances, can't we make an alternative? And can't the fisherman use some other type of bait? These poor crabs are so slow that anyone can grab them, and they really have no defense against us. Please save their species.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.
During a time when the federal government is weakening acts like the Endangered Species Act, it comes down to the states to protect our natural resources. Horseshoe crabs are ancient creatures that have existed long before us, and they deserve to be able to exist. Species are especially threatened now due to climate change and human actions, anything we can do to ease the pressures on threatened species will be beneficial. Massachusetts is often the leader of science-driven policy and leads other states to follow suit. I urge you to adopt this lowered annual quota and set a standard for other states to follow.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mrs. Cynthia Sauer

I am 52 and still get such a thrill when I see a horseshoe crab when walking along a seashore. Simply put, it is an extraordinary creature. It is odd, beautiful, ancient, and although it looks somewhat ominous, it is harmless to humans. I first saw a horseshoe crab as a child and want to be sure that future generations can continue to experience and enjoy seeing these animals up close.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

During last year's spring International Shorebird Survey, I watched several species of shorebirds, in brilliant breeding plumage, feeding on horseshoe crab eggs, as they were being laid. It reminded me how important it is to preserve these species to engage in their ages-old behaviors. I hope you will likewise make such preservation a regulatory priority.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mr. Justin Anderson

Feb 26, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

We deserve to know that our children will see as many horseshoe crabs and shorebirds at the beach as we have. Don't allow a few people to ruin our seashore ecology for money.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mr. Michael McCarthy

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. Rhonda Lyons

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

I lived 12 years on Cape Cod, and served 3 years on the Town of Brewster Coastal Committee. In that time frame I saw the population of these crabs decrease dramatically.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

The use of this resource as bait is a relic, not a necessity, please alter the quotas.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Feb 26, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

I think it's important to acknowledge that this is an animal that has been coming to beaches around the world for 250 million years. That is truly impossible to comprehend. This past summer I spent a good amount of time just watching these wonderful creatures more around and attempt to mate in the beaches around Eastham, MA. It was truly magical to witness. There is no value that can be placed on sharing the world with an abundant diversity of creatures, many of which have been around far, far longer than us humans. Please protect horseshoe crabs for current and future generations.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

There are alternatives available now to crab's blood. Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

This is an unpleasant choice. Reducing the number of horseshoes crabs used for bait is terrific. The whelk fishery is essentially dead and killing crabs for a dying whelk fishing industry is senseless.

I do urge you to reduce, rather than increase, the number of crabs used for biomedical harvesting as well. A synthetic replacement for amoebocyte lysate is available and wealthy drug companies can easily afford to transition to the new product and complete the necessary comparison studies. These crabs are harvested from one area, taken elsewhere to be bled, then tossed back into the ocean somewhere, if they survive the bleeding. It's cruel and unnecessary.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Dr. Donna Cooper

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.
I have been observing horseshoe crabs for over 73 years. They are an integral part of the Massachusetts shoreline and have their place in its ecology. It is important to preserve this. Witnessing the mating in May is a magical and primal sight to behold and something we should honor and protect, not destroy.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crabs have been around since the dinosaurs and are crucial to the circle of life of the ocean & sea birds. Please help protect them so that future generations get to admire them and how they are connected to other species. There is no need to catch them for bait anymore and there is also no need anymore to bleed them since we have other viable alternatives available. Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mrs. Christin Eigenmann

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Using horseshoe crabs as bait is cruel and wasteful, however, I also do not agree with the biomedical use of horseshoe crabs, which is also cruel. They should be protected, period. It makes no sense to favor one cruel exploitation over another:

1. The Procedure: Crabs are brought to labs, restrained, and often have their hearts pierced to drain their bright blue, copper-based blood, a process that takes about eight minutes.
2. High Mortality & Stress: While many are returned to the sea, a significant percentage die from the stress of the procedure, transportation, and blood loss.
3. Long-term Effects: Studies show that bled crabs are only half as likely to come ashore to breed, severely impacting their population.
4. Impact on Ecosystems: The declining population of horseshoe crabs directly threatens shorebirds, such as the endangered red knot, which rely on the crabs' eggs for food during migration.

Nearly 1 million horseshoe crabs are taken from the wild every year and used for their blue blood, which contains a special protein that can test for contamination of medical products. Once captured, they are transported to laboratories, where they are strapped into restraints.

They are pierced through the heart so up to one-third of their blood can slowly be drained before they are returned to the ocean. After this ordeal, these animals are often too weak to fend for themselves in the wild; many are left dead or injured.

There are synthetic alternatives to the biomedical exploitation of horseshoe crabs:

*Recombinant Factor C (rFC): A synthetic, animal-free alternative exists that is equally effective at detecting contaminants.
*Changing Standards: The U.S. Pharmacopeia has issued guidance to encourage using synthetic alternatives over animal-derived LAL, potentially reducing future reliance on the creatures.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. Deborah Bigwood

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

I first vacationed on the Cape with my parents on the Cape in the 1970s. We regularly saw horseshoe crabs in the Bay. More recently, I have worked as a volunteer for Mass Audubon's Wellfleet Bay Wildlife Sanctuary monitoring horseshoe crabs during spawning season. I was shocked to see how few crabs we observed.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds such as red knots are among the most rapidly declining group of birds and need horseshoe crab eggs to survive their migration of thousands of miles to their breeding grounds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mrs. Christine Doyle

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Dr. Oscar Moradei

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.
When my children and grandchildren were young we would walk the beaches around Winsegansett pond and find many recently shed horseshoe exoskeletons. These always created a sense of awe in the children as they tried to figure out how they got out of the shell. We would occasionally find an adult healthy and happy in the surf. In recent years,a walk in the same area finds none of these. The terns and sandpipers in the area have also left. Steps should be taken to restore this once vibrant area and I believe the horseshoe crabs played a major role in that process.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

As a family that vacations down the Cape each summer, quite close to Monomoy, we absolutely loves seeing the horseshoe crash each year as we kayak in the beautiful sañt marches. They are an important part of a very delicate, endangered part of the marine ecosistem our Commonwealth has the great privelwg of caring for.

Please do everything in your power to protect these naciente creatures.

Thank you.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. Elana Katz Rose

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

I have observed horseshoe crabs on the shores of Nantucket Sound for over 50 years. I try to catch May spawning near Stage Harbor when I can. My personal experience is that there are less today then when I started observing them. We need to regulate their harvest and bring their numbers to a sustainable level for future generations.

Horseshoe crab eggs are also a crucial resource for migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebird numbers are declining drastically.

Harvesting the crabs for the biomedical industry and bait must continue to be limited. Thank you for increasing protections for this amazing creature.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

As a lifelong Massachusetts resident, I spent much of my childhood summers on Breakwater Beach in Brewster, MA. As the largest tidal flat in North America, it was home to a multitude of plodding, prehistoric Horseshoe crabs (as well as clams, mussels, hermit crabs, and so much more). In recent years when I venture back to the area, I am not able to find Horseshoe Crabs as they have been harvested to near depletion. When I discovered as an adult that the animals are harvested for their blood, it broke my heart that they were being taken out of habitat, hooked up to machines that bled them, and then unceremoniously dumped back on the beach, with 30% of those not surviving the ordeal. Unless we make a change, now, these 'living fossils' will go the way of the Bachman's warbler and the dodo, leaving shorebirds without an important food source, and our Massachusetts coastline without one of its oldest residents. Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds at this time. Please help save these ancient creatures by disallowing their population to be decimated by us.

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. Kathryn Kaufman

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.
I am a recovering cancer patient, and have also been a fisherman. Watching crabs being harvested is appalling, whether for bait or for research. People catch crabs and hurl them into to the boat with no concern for injuries to the animals. The end use doesn't make the harvest more humane, because ultimately it is all about the money they expect to get. Supposedly there is a premium paid for alive specimens, I don't know. Also, is there a control on bringing them from another state? Regulation definitely needed.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mr. Peter Gailitis

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

All wildlife is very important to me and my family, and we love the shorebirds. But we care equally about the horseshoe crabs and look forward to the day when we completely phase out the unnecessary and unsustainable bait harvest. And although we find the biomedical harvest less destructive than the bait harvest, we strongly believe the biomedical industry should transition to use of synthetic alternatives.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Every summer (48 and counting) my family boats on the Essex River. I live looking for horseshoe crabs on the back side of Crane's Beach and on Choate Island. It is always so exciting to see live ones walking in the water. There often malted shells as well and it's so fun to collect them and to have pretend sword battles with my kids on the beach. I Remember as a kid learning how horseshoe crabs were basically unchanged for millions of years ago, and how they had roamed the Earth when the dinosaurs did.
Please work to protect these magnificent creatures so that future generations can also be delighted by them. Thank you.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. Caitlin Merrill

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds. The stability of a precious natural ecosystem is as vulnerable as rows of dominoes that can fall at any moment - it is imperative we take action where possible, and we must do it quickly. Restricting our impacts on the populations of a species (who's been on this planet way longer than we have!) is a responsibility we have to protect the plant and our finite resources.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Aside from playing a key role in the survival of a number of migratory shorebird species that consume their eggs to fuel their flights north, horseshoe crabs are themselves environments. Scuds, ghost anemones, Asteriids, snail furs, blue mussels, barnacles, sea strawberries, seal lettuce, red beard sponges, eastern oyster, northern rock barnacles, skeleton shrimps, sand builder worms, bushy bugulas, hard tube worms, flat worms, oyster drill eggs and Agardh's red seaweed all make the carapace of Limulus polyphemus their home.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mr. Brian Walsh

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a major food source for fish and migratory birds, including many endangered ones. The adults also serve as prey for conch and sharks. Horseshoe crabs are therefore a crucial part of the food chain. Additionally, their unique blood helps develop drugs.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Dear Mr McKiernan,

I am writing to urge the DMF to adopt the proposed changes to horseshoe crab harvesting regulations. Reducing the bait quota in favor of the biomedical harvest is a common-sense move that will immediately protect 28,000 crabs annually.

However, I view this as a starting point rather than a final solution. The practice of using horseshoe crabs as bait is outdated, and we should be prioritizing the recovery of the species over an unsustainable fishery. Our shorebirds are in a period of rapid decline, and they cannot afford for us to be "middle of the road" on habitat protection. Let's move forward with these regulations and continue working toward restoring the population to its historic levels.

Sincerily,
Stefan Sawadsky

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. Lydia Smith

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds, facing multiple pressures. Let's help them eliminate one of these pressures in Massachusetts. How terrible if shores lack birds.

Medical harvest is unnecessary and OUTDATED now that researchers have developed medications based on similar compounds as those found in horseshoe crabs' blue colored blood. Your vote will give children and grandchildren the chance to be amazed by these living fossils that look like living football helmets. What a shame if beaches are just sand, and if crabs and birds that took hundreds of millions of years to evolve leave us beaches that are bare of all but sand. Nature is our mother, caring for her protects our life in so many ways.

Please consider voting to protect crabs and birds on the beautiful, living shores of Massachusetts.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. Katherine Wheeler

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Yet these birds, and the waters that support them, are among the chief tourist attractions of Massachusetts. I see this where I live on Cape Cod, especially in Wellfleet. People from all over the globe come to Cape Cod for their vacations, and and many will eventually purchase a home for seasonal or year-round residency. This brings in tax-revenue, business income, and builds a resilient economy based on our legendary natural beauty.

The Horseshoe crabs are essential for the success of our shorebirds, and ultimately our natural attractions - which are vital to the Masschusetts economy.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mr. Shawn Vallereux

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crabs are some of the most unchanged and ancient arthropods and are considered "living fossils". Destroying such a unique and long lived species would be a devastating blow to the natural history of the planet.
Additionally, Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds and protecting these vulnerable species protects critical ecosystems as a whole.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Miss Emma Puhalski

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

I have volunteered to monitor horseshoe crab populations and it is clear they are in vastly diminished numbers since I was a child (50 years ago). Horseshoe crabs aren't a throw-away species: they provide food for many species and have survived for millions of years. They should be protected.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

I have long known of and appreciated the reality that Limulus Polyphemus, a near-dinosaur, is not just a marvelous creature but also a critical part of the natural ecosystem above and beyond its importance in medical research. But let it be noted that, as "lab animals" living in their natural habitats, horseshoe crabs have contributed to the saving of countless human lives.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. Kimberly Coale

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

I used to regularly see Horseshoe crabs in the shallows of Pavilion Beach in Ipswich. Now one is a rare event. This proposal is a step toward the population recovery. Better would be to also eliminate the harvest by the pharmaceutical industry. There are alternatives.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds. It is absolutely horrendous that so many horseshoe crabs are murdered for bait and for blood letting. ELI Lilly has shown they are good stewards of the environment by transitioning to synthetic alternatives and are already using 80% synthetics. There is NO reason why Charles River laboratories and Associates of Cape Cod can't do the same as it is absolutely despicable. Horseshoe crab numbers have declined horrendously

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mr. Donald Henrich

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are an important food for global migratory birds; rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Increasing and maintaining sufficient populations to feed shorebirds will help sustain the populations of some of the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. Judith Nardacci

But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Using Horseshoe Crabs for bait makes little sense as they decline in overall numbers. Let's not be the generation that destroys a last remnant of one of the oldest ecological lineages. I do support continued harvest for medical purposes, but would like to see that managed in a way that doesn't further deplete the species.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

My grand kids have been very concerned about preserving the horseshoe crabs on Cape Cod. They have been learning about them since they were very little and are even more concerned 14 years later! They told me to ask: Isn't there something that isn't "pre-historic" that can be used for bait? And I am adding: for Heaven's sake!?

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

I have seen the number of horseshoe crabs decline over the years on Cape Cod as I have been walking the beaches. We need to protect them from harm or death due this blood leading process,. There are other ways to create the necessary medications that humans need without harming the horseshoe crabs.

We have the technology to do it so let's use it.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial food resource for global migratory birds, such as the threatened Red Knot which migrates extreme distances. They have been seen feeding on the crab eggs in places where harvesting the crabs is forbidden.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. Gail Boyajian

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Dr. Igor Zlokarnik

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Dear Director McKiernan,

I am writing to strongly support the DMF proposal to limit the annual bait harvest of horseshoe crabs. Saving an estimated 28,000 horseshoe crabs per year is a meaningful and necessary step. However, I urge the state to move more decisively toward phasing out the unnecessary and unsustainable bait harvest altogether, while encouraging the biomedical industry to accelerate its transition to effective synthetic alternatives.

Horseshoe crab eggs are a vital food source for global migratory birds. Rare shorebirds have been documented feeding on these eggs at Monomoy, where horseshoe crab harvest is prohibited -- a clear indication of the ecological importance of protecting these populations. Shorebirds are among the most rapidly declining groups of birds worldwide, and continued pressure on horseshoe crabs only compounds this crisis.

Massachusetts has an opportunity to demonstrate strong environmental leadership by taking meaningful action now. I respectfully urge you to adopt the proposed limits and to continue advancing policies that ensure the long-term protection of horseshoe crabs and the species that depend on them.

Thank you for your time and consideration.

Sincerely,

Tammy Nohelty

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crabs are an iconic and prehistoric species that serve as a lynchpin for biodiverse marine ecosystems, and their eggs are a crucial resource for global migratory birds. Massachusetts allows them to be harvested for bait, despite populations that have not recovered to historic levels.

The state is proposing new rules that would reduce the number of horseshoe crabs that can be fished for bait, as well as reducing the biomedical industry's reliance on the bait harvest. The animals bled for the biomedical industry are returned to the water, and while there is some mortality, this is much less than the 100% loss of crabs harvested for bait.

Division of Marine Fisheries (DMF) Director Dan McKiernan proposed to lower the bait harvest quota from 140,000 crabs per year to 100,000 crabs per year and proposed to increase the biomedical harvest quota from 200,000 crabs per year, to 280,000 crabs per year.

Assuming a 15% mortality rate for crabs caught for bleeding, this would result in a net decrease in horseshoe crab mortality of at least 28,000 crabs.

Additionally, the proposal is specifically designed to decrease the biomedical industry's reliance on bait catch, tempering an important driver of demand for that fishery. There is no regulatory path forward to ending the bait harvest in Massachusetts that doesn't address short

term demand from the low-mortality biomedical fishery. The product they make is still in high demand by drug and medical equipment manufacturers.

Director McKiernan's memo points out that if we want to manage horseshoe crabs for abundance, then the focus should be on mortality, and not strictly on harvest catch limits.

While this is a step in the right direction, the state should move decisively toward phasing out the unnecessary and unsustainable bait harvest and the biomedical industry should transition to use of synthetic alternatives.

The best way to end using horseshoe crabs as bait entirely is to take an approach that prioritizes winding down the bait fishery.

DMF's proposed quota reallocation embraces that approach, reducing the allowable catch by nearly 30% for an industry in which every animal that is caught dies.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. Emme Carroll

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Horseshoe crabs as particularly meaningful to me as I remember fishing the coast with my father and seeing crabs all over the place during their mating season and understand how important they are to the ecosystem. Their habitat is constantly under threat of development and human interference which makes regulation like this, to protect their numbers, all the more important.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

This proposal is a reasonable first step to restoring this unique species, which is integral to the food chain of migrating shorebirds and performs other ecological services in coastal waters. The species could be seen on many beaches only 50 years ago; now it is rare. Such over-utilization of a species is not the kind of environmental legacy that Massachusetts should support.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Moreover, horseshoe crabs are amazing in their own right as living fossils on our beaches. They have survived five mass extinctions! At a time when species are decimated by human overhunting, etc., it is vastly important that horseshoe crabs do not disappear alongside them.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mr. Cat Dossett

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mrs. Shelda Semerjian

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a vital resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. kathryn roy

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mrs. Nancy Solomon

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. Cornelia Hoskin

Feb 25, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds. Both shorebirds and horseshoe crabs are already threatened by climate change and coastal development. The additional stressor of harvesting horseshoe crabs for bait is unnecessary and may have devastating consequences, including collapsing the food chain that supplies the migration of shorebirds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Miss Julia Breed

But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

During my last visit to Eastham I watched a few horseshoe crabs leisurely slide through the coastal water. What a marvel!

And now to learn that the crabs' eggs are a crucial resource for global migratory birds, it is imperative that you act on protecting them.

Shorebirds are among the most rapidly declining group of birds. Can you imagine a visit to the shores without seeing a single healthy bird?

I don't want to.

And I don't want my grandchildren not being able to respect and honor them.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

There isn't really a cogent reason to continue harvesting horseshoe crabs any longer now that researchers can use *synthetic* Recombinant factor C and recombinant cascade reagent to test pharmaceuticals for endotoxins without the use of horseshoe crab blood. Reducing the harvest quota will slowly help horseshoe crab populations rebound, which will also have an extremely positive effect on sea bird populations that depend on their eggs for fuel during migration periods.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Dr. Kelly Carlson

But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

I first learned about horseshoe crabs as a child in the early 70s since they were abundant on Popponesset Beach. It wasn't until recently that I learned that they are harvested for bait and for use in the biomedical industry, logical explanations of the decline in their population.
Horseshoe crabs are important to migratory birds and the local ecology. I'm writing to urge you to adopt the proposed regulation changes.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Feb 21, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

We as humans have created most of the dangers to our wildlife, so it is up to us now to be a voice for the voiceless. Horseshoe crabs have been around and virtually unchanged for millions of years, they are now listed on the IUCN red list as Vulnerable. They made it through the age of the dinosaur, should they not also make it through the age of the human? Please use your power for good!

Horseshoe crab eggs are a crucial resource for global migratory birds, like endangered Red Knots, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. Sarah Thornington

Feb 21, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

I grew up searching for Horseshoe crabs in tidal ponds and at low tide. When my kids were my age, I noticed that we didn't see them anymore or if we did, it was rare. The Horseshoe crab is a vital animal to our ecosystem and should not be used for experiments or bait.

Please... please do something!

-Camilla Thompson

As a lifelong visitor to Cape Cod and a property owner for 20+ years, I can share first hand experiences with watching shorebird breeding and migration through Massachusetts' coastal areas. Horseshoe crab eggs are vital nourishment for these birds to maintain healthy populations. Horseshoe crabs themselves are wonderful to observe with their prehistoric looking bodies and their seasonal returns for breeding. They are the delight and wonder for countless visitors and children.

These creatures are special and they serve and important purpose worthy of further protection.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mrs. Carol Goslant

Attention: Dan McKiernan, Director, Massachusetts Division of Marine Fisheries

Dear Director McKiernan,

I am writing as a summer Cape Cod resident to comment on the Division of Marine Fisheries' current proposal to change horseshoe crab quotas.

Given that DMF's own proposal acknowledges declining bait demand while expanding the number of horseshoe crabs used for biomedical purposes, and that horseshoe crabs have not fully recovered statewide, **this is an appropriate moment to end the use of horseshoe crabs for bait and maintain the existing 200,000 biomedical quota, rather than expand overall harvest pressure**.

Horseshoe crabs are a public trust resource with critical ecological value, and management decisions should prioritize conservation, transparency, and long-term population recovery.

Thank you for considering my comments.

Sincerely,
Gretchen L Mueller

Feb 20, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crabs, like so many other wildly unique species to our coastlines are rapidly declining in numbers. I grew up playing with the shells on the beach and I haven't seen more than a piece of a shell in years. My kids have never seen a live horseshoe crab.
They are increasingly fished/hunted for a growing number of uses and I wholeheartedly agree that the culling needs to be limited and managed.

Thank you for your action to protect this unique creature.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Feb 20, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. Stephanie Mitzenmacher

Feb 20, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.
These ancient animals are critical to the ecosystems of the Cape Cod Bay and the Nantucket Sound marsh/estuary lands. They are not necessary in the fisheries BAIT equation, so much else is available. Enough natural selection occurs to keep the population in balance. Please change the regulations to favor these 400 million year survivors.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Feb 20, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

They are also evolutionary wonders that need our protection.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mr. Daniel Hudon

We Need to Leave God's creatures alone THEY have a VERY crucial role in the food chain and to disrupt their role would endanger another precious creature. This needs to stop its crazy we have to protect animals when Human common sense should prevail and know its wrong and will have consequences...
PLEASE Stop This and Please make sure it's Enforced.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mrs. Bonnie Samia

But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

I work with kids and they love learning about horseshoe crabs. We go to the beach every day at the summer camp I run, and the kids find horseshoe crabs swimming in the shallows. Their prehistoric shape gives kids a feeling of excitement and discovery. Whoooaa!! They say a they muster the courage to pick up the crab and show their friends. Horseshoe crabs are so docile and defenseless that they are a great way to help kids learn how to safely and gently handle animals. They offer a low risk opportunity for kids to connect with nature and become familiar with handling animals

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Feb 19, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mrs. Megan Labrie

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crabs are essential to not just ocean life, but human life too. They're wonderful, intelligent, and unique living fossils that need to be protected for everyone- human and animal's- wellbeing. There are other sources of bait that fisheries can use that won't put this species at risk and I urge you to steer them that way. A creature that's been around as long as it has (millions of years!) deserves to continue sticking around for generations more to come.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mr. Zephyrus Johnson

Feb 19, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crabs have always been an exciting find on the beach for my family and I. I've always enjoyed moving any stranded ones back to the water or flipping them over when they're stuck on their backs. However, even with just my individual experiences on the beaches of Massachusetts, I've noticed that I don't see them much anymore. Sometimes I go a full year without seeing a single living horseshoe crab.
When I was younger, I assumed it was just bad luck and I kept missing them. However, with the bait harvest being known to bring populations down in New England more than the rest of the Atlantic coast, it's important that we can address this now and keep allowing kids to experience the joy of stumbling across such a strange and ancient creature. Massachusetts has no business falling behind on protective measures for our planet!

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.
Their population decline is obvious everywhere along the coast that my family visits. From seeing live horseshoe crabs in abundance 20yrs ago to now only finding an abundance of dead ones along the beach. It's a rare occasion to find live ones to show our children. We need to do better to respect this beautiful species.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mrs. Amy Perry

Feb 19, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Additionally, they strike wonder in young and old alike. I have taken many folks on marsh walks and kayak rides. The horseshoe crabs have neber een seen by many and a total highlight for them. As a sixth grade teacher, I have brought molted shells and the remains of an expired crab into the classroom. The majority of children are unfamiliar with them. When I explain how old they are, the students are stunned.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crabs are an integral part of our states ecosystem. They are also a deeply inspirational subject for the kids I teach on a daily basis. In my tenure as a teacher, each year I hear countless stories of children who were inspired to be connected to the nature in their communities because they grew up with, or visited the horseshoe crabs as children and young adults. Those children are now artists, biologists, scientists, and conservationists.

It is not at all surprising that such a special and unique animal can positively shape the experiences of so many in our state. I implore you to protect this species and relieve them of the pressures they experience outside of our rapidly changing environment.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

During my lifetime I have noticed a sharp decline in the population of horseshoe crabs.

Please consider this alternative to blue blood!

Dominique DeMarsh

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Mrs. Dominique DeMarsh

Feb 19, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.
Please help save these amazing creatures. They have been around for 300 MILLION years and are essential part of our oceans ecosystem.
We are losing so much already, with the trawlers harvesting tons and tons of fish daily, the depletion of kelp forests and coral, the warming of our oceans, the dumping of plastics and other trash into our water.
We need every little bit we can save.
Thank you.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. Lisa Rahn

Feb 19, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

It's appalling how the population of horseshoe crabs has declined. We used to see them along the shore and marsh, but it's very rare now. They was such disregard for them that they have been used for fertilizer and bait. They are so much more important to the ecological food chain and such iconic creatures. Stop giving hunters and fishers such freedom to destroy populations of animals.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Ms. Pamela Mansfield

Horseshoe crabs have been around for millions of years. There are an important part of the ecological web. In Sandwich Massachusetts we used to see many more horseshoe crabs than we see today it's anecdotal, but I think it shows their decreasing numbers. Please act to protect them.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Subject: Withdraw proposed increases in the horseshoe crab biomedical harvest quota
Date: Saturday, March 7, 2026 6:06:31 AM

CAUTION: This email originated from a sender outside of the Commonwealth of Massachusetts mail system. Do not click on links or open attachments unless you recognize the sender and know the content is safe.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

I have been counting shorebirds that show up for horseshoe crab eggs to fuel their continued migration from South America to the Arctic breeding grounds every spring around May every year at the Delaware Bay in New Jersey and brought my grandson (who's now 19) there every year
for many years, so this issue is important to me no matter what the state.
Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

Some of my earliest memories are of seeing horseshoe crabs; threats to their viability are thus especially meaningful to me. And make no mistake, the proposed increase is a real threat.

Here are some of the details: The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

Dear Massachusetts Division of Marine Fisheries,

As a nearly 63 year resident of Massachusetts and as a lover of our state's lands and waters and the life they sustain, I am asking you please to withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival. SO NOW EVIDENTLY THIS STATE WANTS TO BE A NAIL IN THE COFFIN OF A SPECIES THAT SURVIVED METEORS, CLIMATE CHANGES, ETC., ETC.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' totally dishonest and hypocritical rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a grotesque loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies WHOSE OWN RESEARCH SHOWS we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places antediluvian Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends. WHAT IS THE MATTER WITH THIS PICTURE?

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives.

And, for simply selfish reasons, I have been enjoying seeing horseshoe crabs in MA since the 1980's and would hate to think that my state government is facilitating their demise.

Dear Massachusetts Division of Marine Fisheries,

I'm writing to you about the horseshoe crabs. With a synthetic alternative approved and available, there's absolutely no justification for increasing the allowable limit on the catch indeed, it should be just the opposite - limit the catch even further.

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs. I spend every summer walking out on the flats in Barnstable Harbor, and have seen the populations fluctuate. These are incredibly special animals, and still need to be protected.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Dear Massachusetts Division of Marine Fisheries,

I know this must seem like a niche issue, but it is not. These humble but ancient beings are subject to abusive biomedical practices, while there are synthetic tests that accomplish the same ends. I saw a photo of one of the extraction labs with rows of crabs affixed to supports while they are bled. It was horrifying and utterly unnecessary. Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Dear Massachusetts Division of Marine Fisheries,

It seems utterly wrong to allow such ancient and resilient creatures to be extirpated for any reason, even if the goal is medical research. And new advances make horseshoe rap blood no longer necessary. Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs. There are very reasonable alternatives for all of their "uses" except for their rightful place in the ecosystem and in support of migrating birds via their eggs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission. This is irresponsible and absurd.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.
