And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Too many have been killed -- their function in aquatic ecosystems are essential and from Massachusetts beaches they need not be taken and killed for biomedical research. Alternative solutions for their blood are animal free synthetic substances.

An example of their place in the ecosystem: migrating birds, such as the Red Knot (Calidris canutus), feed on their eggs in preparation for long migration flights from South American to their breeding site in the arctic.

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

Please enable these imperiled creatures to thrive: not be killed for laboratory research and testing.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Dear Massachusetts Division of Marine Fisheries,

As a US citizen and resident of Massachusetts, I urge you to withdraw the proposed increase in the biomedical catch quota for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by over-harvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Synthetic tests are now FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. To Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs. A higher catch quota is not needed given advancements in science that create synthetic substitutes.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs. We should be joining in the efforts of Connecticut and New York and further limiting or even banning these harvests.

This proposal places Massachusetts even further behind neighboring states. Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Dear Massachusetts Division of Marine Fisheries,

I live on Cape Cod. I find it unconscionable that you would push to the very limit of its viability a species so endemic to the cape. Please be courageous enough to halt this proposition.
Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether. Thank you.

Kind Regards,
Sheila Miller

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe.
Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.
In Pleasant Bay the number of young horseshoe juveniles has dropped dramatically since I was young in the 1960's. We have been counting each season and are shocked at how few are seen in recent years.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.
Thank you for your consideration and your work!

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Dear Director and Members of the Division of Marine Fisheries,

I am writing to respectfully urge you to withdraw the proposed increases in the horseshoe crab biomedical harvest quota.

Horseshoe crabs are an extraordinary and ancient species that play a vital role in Massachusetts' coastal ecosystem. Over the past several decades, their populations have declined significantly. Increasing harvest pressure now — even for biomedical purposes — risks further weakening a species that is already under stress.

I recognize the importance of protecting human health and ensuring safe drug testing. However, synthetic, animal-free alternatives such as recombinant Factor C have been approved by U.S. regulators and are increasingly used by manufacturers. Given the availability of these alternatives, Massachusetts should be accelerating the transition away from reliance on wild horseshoe crabs, not expanding the number that can be captured and bled.

This issue also affects the broader ecosystem. Horseshoe crab eggs are a critical food source for migrating shorebirds, including the federally threatened red knot. As environmental pressures mount from climate change and habitat loss, it is especially important to avoid adding preventable stress to species that underpin coastal food webs.

Massachusetts has long been a leader in science-based resource management. With neighboring states strengthening protections, I urge the Division to demonstrate similar leadership by withdrawing the proposed quota increase and prioritizing conservation and transition to animal-free testing methods.

Thank you for your consideration and for your stewardship of our marine resources.

David

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.
I have seen the radical decline in the horseshoe population over the last 2 decades. Very few come in on the bay side of Cape Cod. In the 1960s their arrival was spectacular.
It is not necessary to bleed the crabs, their are synthetic substances now that can replace the horseshoe crab blood in safety testing of medical equipment. I believe these synthetics are used in Europe.
No one or no company has the right to squander our resources, It is embarrassing that Massachusetts is so behind in passing protection measures where other New England states have done so. The American horseshoe crab has survived 450 million years multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

We need to stop lagging behind Connecticut and New York as far as horseshoe crab protections. Do not increase the horseshoe crab catch. My twelve year old says “please just look at the science. This blood isn’t medically necessary anymore because there are synthetic alternatives. It isn’t needed to save human lives anymore, so let’s save horseshoe crab lives.”

If a twelve year old can read through the data and understand this, this division can as well and act to protect our resources.

They do not belong to companies. The profit is not sustainable. But a healthy ecosystem will sustain all of us.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

Massachusetts, my state, prides itself on conservation and scientific leadership. I urge the division to prioritize conservation and science by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives, by implementing plans to phase out the catch altogether.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by over-harvest in the 1980s and 1990s. Populations remain seriously depleted in our state. Increasing the catch will further threaten the species' survival.

Biomedical harvests of horseshoe crabs have already more than doubled in the past six years: more than 1 million crabs annually according to the Atlantic States Marine Fisheries Commission!

Independent studies show that 30% or more of the crabs perish as a result of the bleeding process or suffer significant sub-lethal effects that impair their ability to spawn.

And another program creates a loophole that obscures the scale of the catch. The rent-a-crab program, which routes bait-designated crabs to biomedical bleeding labs first, adds an additional 100,000 crabs to the blood-harvest total -- a staggering number that undermines conservation goals.

Massachusetts' own biomedical companies' research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Why is Massachusetts not working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs? It makes no sense to destroy a species -- with no justification.

What is more, many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their epic annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends. Neighboring states are way ahead of Massachusetts. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while our state is moving in the opposite direction.

Who is getting paid for this travesty of common sense? You are the Marine Fisheries; please do the job Massachusetts citizens expect of you.

Thank you.

In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs. This is neither necessary or advised and we in Massachusetts are acting like an uninformed and backward part of scientific thought. Animal-free substitutes are readily available and commonly used elsewhere!

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Dear Massachusetts Division of Marine Fisheries,

Horseshoe carbs survived the extinction of the dinosaurs. But they may not survive us. Imagine that.

Horsehoe crab populations have not rfecovered from a human-caused collapsed in the 1980s and 90s. Despite that, you are proposing increasing the allowable catch.

Alternatives are available now for biomedical use. The conservation of this ancient species is important. Please withdraw the proposed increase in the biomedical harvest quota and begin crafting plans to phase out the harvest.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Dear Decision-Makers at the MA Division of Fisheries,

Please stop using our horseshoe crabs for experimental research.

I am appalled that in this era or decreasing biodiversity this practice continues.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Sincerely and Urgently,
Teresa R. Weiner

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

Dear Massachusetts Division of Marine Fisheries,

Horseshoe crabs are amazing. Think how long they have been around. They play an important role in the ecosystem-migrating birds rely on them for food. Scientific research does not need to rely on their blood anymore. So, please, protect them from unnecessary over harvesting.

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

PLEASE withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn. See, e.g., https://urldefense.com/v3/__https://pubs.usgs.gov/publication/70223362__;!!CPANwP4y!QprfoKK9MEuSpK4UDWMyaty431Cxo-eufLPtMvu1K-serby8-MC9u4iZZo1Ox6UXuGdBzxf2mKTcXPpCRFbzNvbFFdV7XuC7zg$

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics, supporting that innovation economy and its value to Massachusetts residents, rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation, scientific and innovation leadership, with innovation and education underpinning its prosperity (See, e.g., the Hamilton Project's The Geography of Prosperity, Brookings). I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Please note that this longer and more detailed version should be the one included in the record. I accidentally hit send before I was completed.

Lastly, please be advised that I am a Massachusetts resident, resident on the coastline, and can attest to the loss of these animals and their importance to migratory birds. I am also a partner at WSGR. I will support any and all environmental organizations and residents on a pro bono basis to challenge this unreasonable, unscientific activity before the courts.

Thank you.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The industry is shifting toward synthetic alternatives for blood testing, such as recombinant factor C. That's what Massachusetts, with its excellent biomedical research facilities, should be doing.

PLEASE!!

Dear Massachusetts Division of Marine Fisheries,

Hello,

In 2020-21 I designed and installed a Horseshoe Crab garden in Boston in front of an internationally known museum: the Museum of Fine Arts. Rimmed in shell, and mounded up it was covered in sedges, corn and beans highlighting Native presence, culture and Bostons identity as an important coastal city that depends on the resources of a healthy ocean.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s.

Massachusetts' rent-a-crab program is still not sustainable. And the bled horseshoe crabs have a very high mortality rate. Shorebirds, fish and other species depend upon horseshoe crabs in the western Atlantic.
This proposal places Massachusetts even further behind neighboring states.

Please withdraw proposed increases in the biomed harvest quota. Please do accelerate the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

I heard someone speak on this subject on the news. This seems to be an area of biomedical testing that has been overlooked and unregulated.

Every species counts.

We do not allow the kind of testing that results in death for other animals. This is inhumane. Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Independent studies show that 30% of the crabs, or more, die as a result of the bleeding process or suffer significant sublethal effects that impair their ability to spawn.

And Massachusetts' rent-a-crab program — which routes bait-designated crabs to biomedical bleeding labs first — creates a loophole that obscures the true scale of the catch. According to local experts, rent-a-crab adds an additional 100,000 crabs to the blood-harvest total, a staggering number that undermines conservation goals.

Massachusetts is home to biomedical companies whose own research shows we no longer need horseshoe crab blood to ensure patient safety. Bleeding companies are marketing the animal-derived agent side-by-side with newer animal-free alternatives. These synthetic tests are FDA- and USP-recognized and are already used in treatments for diabetes, obesity, COVID-19, and many other medicines and vaccines. Massachusetts should be working to accelerate the transition to synthetics rather than increasing the use of horseshoe crabs.

This proposal places Massachusetts even further behind neighboring states. In the past three years, Connecticut and New York have taken decisive action to ban horseshoe crab harvesting, while Massachusetts is moving in the opposite direction. Increasing Massachusetts' biomedical quota by more than 80,000 crabs is a rejection of modern science and regional conservation trends.

Many imperiled shorebirds — including federally threatened red knots — depend on horseshoe crabs to survive. Red knots time their annual migration to coincide with horseshoe crab spawning, feeding on horseshoe crab eggs in Massachusetts to fuel their 19,000-mile journey from South America to the Arctic. As horseshoe crab populations have plummeted, so have red knot numbers.

Massachusetts prides itself on conservation and scientific leadership. I urge the division to prioritize conservation by withdrawing the proposed increase in the biomedical harvest quota and instead accelerating the transition to synthetic alternatives by implementing plans to phase out the catch altogether.

Dear Massachusetts Division of Marine Fisheries,

Please withdraw the proposed increase in the biomedical catch quota in Massachusetts for horseshoe crabs.

The American horseshoe crab has survived 450 million years and multiple mass extinctions, but it has failed to recover from a catastrophic population collapse caused by overharvest in the 1980s and 1990s. Populations remain seriously depleted in Massachusetts. Increasing the catch will impede the recovery of horseshoe crabs in the Commonwealth and further threaten the species' survival.

Already biomedical harvests of horseshoe crabs have more than doubled in the past six years to more than 1 million crabs annually, according to the Atlantic States Marine Fisheries Commission.

Dear Director McKiernan,

I am writing as a Massachusetts resident to comment on the Division of Marine Fisheries' current proposal to change horseshoe crab quotas.

Given that DMF's own proposal acknowledges declining bait demand while expanding the number of horseshoe crabs used for biomedical purposes, and that horseshoe crabs have not fully recovered statewide, **this is an appropriate moment to end the use of horseshoe crabs for bait and maintain the existing 200,000 biomedical quota, rather than expand overall harvest pressure**.

Horseshoe crabs are a public trust resource with critical ecological value, and management decisions should prioritize conservation, transparency, and long-term population recovery.

Thank you for considering my comments.

Sincerely,
Emily Weisgrau

Mar 2, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Miss Emily Isaac

Director McKiernan,

When I was a child on Cape Cod, one of my favorite pass times was to watch the horseshoe crabs along our beaches, and to follow their trails on the sand bars at low tide. It sparked an interest in marine biology which I still follow. But the opportunity to watch these marine creatures is all but gone.

Horseshoe crabs have been in peril for quite some time. Under pressure from fishermen, looking for cheap bait; and private industry, looking to drain their blood. These animals have a significant place in the ecosystem and food chain, their eggs serve as an important source of nutrition for shore birds.

Now, it has come to my attention that the Mass Division of Marine Fisheries is considering a proposal that would limit the use of horseshoe crabs as bait.
However, the same proposal will expand the blood-letting of these creatures.

The blood letting process is NOT a harmless procedure. Not all of those horseshoe crabs survive. This is a creature that has managed to survive millions of years in the ocean. Now, we are allowing it to fall prey to an industry that has an available synthetic replacement for their blood, namely Recombinant Factor C. This synthetic is used by major pharmaceutical companies in the US, Europe and Asia.

Why can't we follow what New York has done? and protect this species?

PLEASE do the right thing by these creatures and other species that depend on them.

Thank you.

Dear Director McKiernan,

I am writing as a Massachusetts resident from Cape Cod, and I wish to comment on the Division of Marine Fisheries' current proposal to change horseshoe crab quotas.

Given that DMF's own proposal acknowledges declining bait demand while expanding the number of horseshoe crabs used for biomedical purposes, and that horseshoe crabs have not fully recovered statewide, **this is an appropriate moment to end the use of horseshoe crabs for bait and maintain the existing 200,000 biomedical quota, rather than expand overall harvest pressure**.

Essentially, this would:

- **expand biomedical exploitation;**
- **maintain bait quotas that exceed actual need;**
- **put Massachusetts out of step with neighboring states; and**
- **ignore unresolved concerns about population recovery**

Horseshoe crabs are a public trust resource with critical ecological value, and management decisions should prioritize conservation, transparency, and long-term population recovery.

Thank you for considering my comments.

Hello Director Daniel McKiernan,

In 2023, the Massachusetts Division of Marine Fisheries capped the biomedical horseshoe crab quota at 200,000 and split that quota evenly between the two existing processors. Now, DMF is proposing to raise the biomedical quota to 280,000 crabs, plus routing an additional 100,000 bait crabs through the rent-a-crab program. to the bleeding facilities. Why?

Massachusetts should end the use of horseshoe crabs for bait. Horseshoe crabs are far too ecologically and medically valuable to be killed for a depleted whelk fishery. Ending the bait fishery would immediately reduce overall mortality, simplify management, and allow the Commonwealth to focus on recovery and conservation.

Synthetic alternatives to horseshoe crab blood exists, bait demand is declining, and conservation-first management is achievable—if Massachusetts chooses to lead rather than lag behind.

Please do not go forward with the Division of Marine Fisheries' proposal to increase the number of horseshoe crab that are allowed to be harvested each year so that their blood can be utilized for medical purposes and testing. There is a synthetic alternative available that has been approved by US Pharmacopeia and supported by Congress.

Respectfully,

Dear Director McKiernan,

I am writing as a Massachusetts resident to comment on the Division of Marine Fisheries' current proposal to change horseshoe crab quotas.

Given that DMF's own proposal acknowledges declining bait demand while expanding the number of horseshoe crabs used for biomedical purposes, and that horseshoe crabs have not fully recovered statewide, **this is an appropriate moment to end the use of horseshoe crabs for bait and maintain the existing 200,000 biomedical quota, rather than expand overall harvest pressure**.

Horseshoe crabs are a public trust resource with critical ecological value, and management decisions should prioritize conservation, transparency, and long-term population recovery.

Thank you for considering my comments.

Sincerely,

Attention: Dan McKiernan, Director, Massachusetts Division of Marine Fisheries

Dear Director McKiernan,

I am writing as a Massachusetts resident to comment on the Division of Marine Fisheries' current proposal to change horseshoe crab quotas.

Given that DMF's own proposal acknowledges declining bait demand while expanding the number of horseshoe crabs used for biomedical purposes, and that horseshoe crabs have not fully recovered statewide, **this is an appropriate moment to end the use of horseshoe crabs for bait and maintain the existing 200,000 biomedical quota, rather than expand overall harvest pressure**.

We are not the only creatures that matter. Horseshoe crabs are essential resources to the marine ecosystem and to migrating shorebirds. Shorebirds are declining rapidly and they need our protection. Migrating from their South American wintering grounds, the birds may lose half their body weight before stopping at feeding areas where horseshoe crabs are laying eggs on the beaches. The birds probe the sand for eggs to fatten up for the rest of their journey. The crabs and birds have been coexisting in this way for countless generations, but our industrial harvesting of crabs is causing them to decline, and there are not enough eggs being laid for the birds' food and the crab's reproduction.

Horseshoe crabs are a public trust resource with critical ecological value, and management decisions should prioritize conservation, transparency, and long-term population recovery.

Thank you for considering my comments.

Sincerely,
Fran Raleigh

Dan McKiernan
Director, Massachusetts Division of Marine Fisheries

Dear Director McKiernan,

I am writing as a Gloucester, Massachusetts resident to comment on the Division of Marine Fisheries' current proposal to change horseshoe crab quotas. I am also a silk painter and Great Marsh Artist, currently co-creating multi-media public performances with Arpeggione Ensemble on the intertwined relationship of horseshoe crabs and red knots, 'Music and Silk: an Ancient Creature and a Shorebird's Survival'.

Given that DMF's own proposal acknowledges declining bait demand while expanding the number of horseshoe crabs used for biomedical purposes, and that horseshoe crabs have not fully recovered statewide, this is the right and proper time to end the use of horseshoe crabs for bait and maintain the existing 200,000 biomedical quota, rather than expand overall harvest pressure.

Horseshoe crabs are a keystone species and all management decisions should prioritize conservation, long-term population recovery, and thoughtfulness in ensuring the continuation of this vital species for preserving coastal ecosystems and biodiversity.

Thank you for considering my comments.

Yours sincerely,

Susan Quateman
Gloucester, MA.

Dear Director McKiernan,

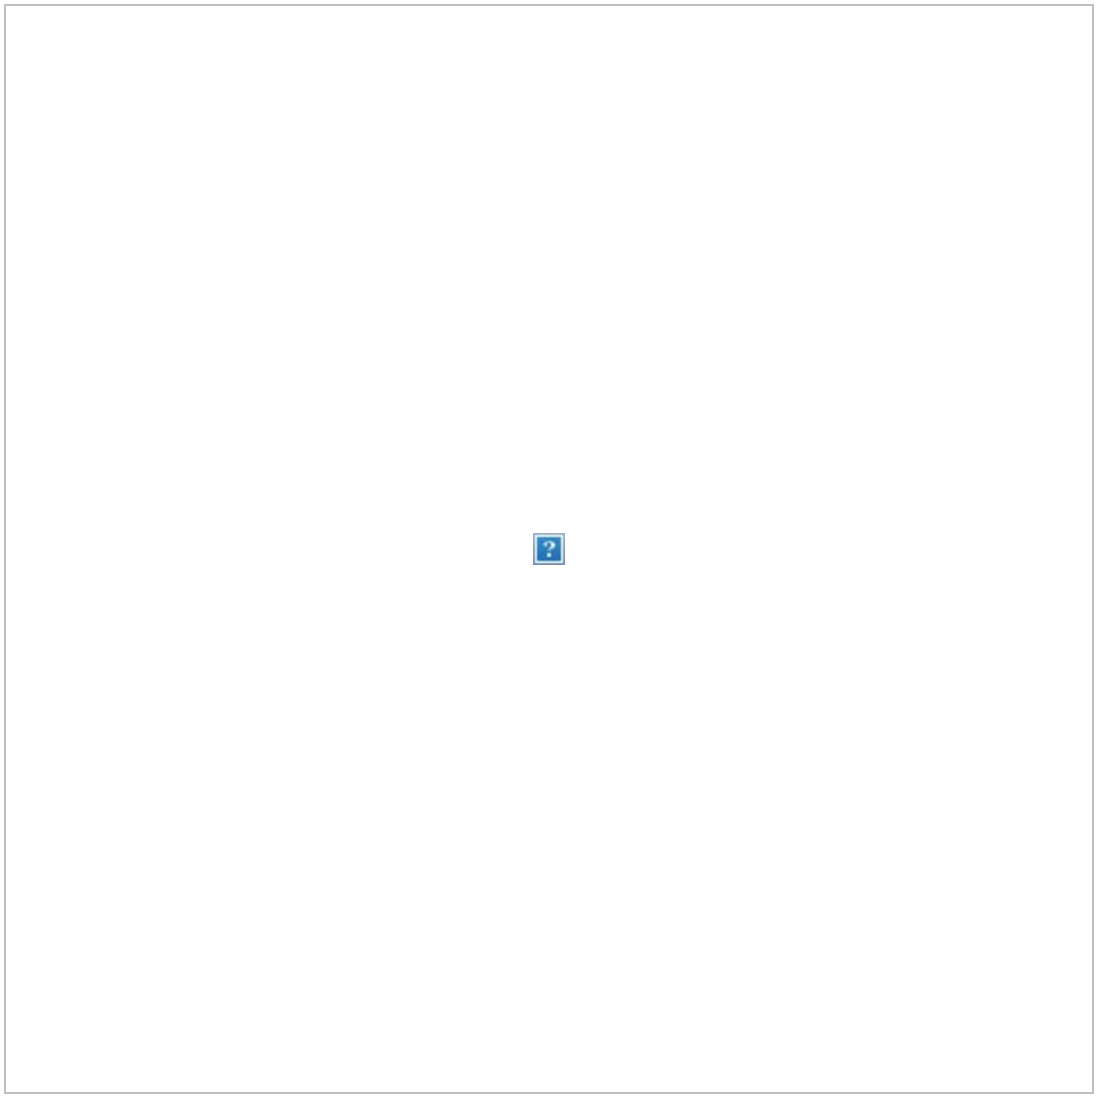
I am writing as a Massachusetts resident to comment on the Division of Marine Fisheries' proposal to revise horseshoe crab harvest quotas.

Given that the proposal itself notes declining demand for bait and simultaneously expands the number of horseshoe crabs allocated for biomedical use—at a time when the statewide population has not fully recovered—this is the appropriate moment to end the use of horseshoe crabs for bait and to maintain the existing 200,000-crab biomedical quota rather than increase overall harvest pressure.

Horseshoe crabs are a public trust resource with significant ecological importance, and management decisions should reflect a commitment to conservation, transparency, and long-term population recovery.

Thank you for your serious consideration of these comments, especially at a time when many long-standing environmental protections are being weakened or eliminated.



Sincerely,

Craig Maser

Attention: Dan McKiernan, Director, Massachusetts Division of Marine Fisheries

Dear Director McKiernan,

I am writing as a Massachusetts resident to comment on the Division of Marine Fisheries' current proposal to change horseshoe crab quotas.

Given that DMF's own proposal acknowledges declining bait demand while expanding the number of horseshoe crabs used for biomedical purposes, and that horseshoe crabs have not fully recovered statewide, **this is an appropriate moment to end the use of horseshoe crabs for bait and maintain or reduce the existing 200,000 biomedical quota, rather than expand overall harvest pressure**.

Having lived near the Delaware River estuary for many years the experience of seeing a protected population of horseshoe crabs flourish and to be able to observe the millions of endangered migrating shore birds feeding on the eggs is a life-changing experience. To then move back to Massachusetts and learn that until last few years there was no protection for the horseshoe crabs at all. Massachusetts is still in the relative dark ages in our treatment of this ancient and important animal. Furthermore, there is now developed a synthetic replacement for the horseshoe crab blood. The horseshoe crabs are a public trust resource with critical ecological value, and management decisions should prioritize conservation, transparency, and long-term population recovery.

Thank you for considering my comments.

To: Dan McKiernan
Director, Massachusetts Division of Marine Fisheries

Dear Director McKiernan,

I am writing as a Massachusetts resident concerned about the future of Horseshoe Crabs and how it will be affected by the Division of Marine Fisheries' current proposal to change horseshoe crab quotas.

After what seemed like progress last year, I was surprised and disturbed to see the current DMF proposal going in the wrong direction entirely. Instead of helping to rebuild horseshoe crab populations in the state when it is known that they are still recovering from past over-harvesting, the proposal puts even more of them at risk. While the bait quota would be reduced, the new number still exceeds the actual bait needs as stated by the DMF. It makes no sense to continue supporting a failing industry to the detriment of another very important species, the horseshoe crab.

As far as biomedical harvesting, the proposed quota is a dramatic increase for no valid reason. Pharmaceutical companies are increasingly transitioning to a synthetic alternative to horseshoe crab blood, so the proposal to significantly raise them is a cruel and questionable move that would only benefit commercial interests. Some crabs do not survive the process at all, and the ones that survive it are left in a weakened state to the detriment of their health and spawning success.

Rather than using this moment to reduce pressure and rebuild horseshoe crab populations statewide, DMF's proposal moves in the opposite direction—prioritizing private commercial interests over long-term population recovery, ecosystem health, and resilience.

Horseshoe crabs are a public trust resource with critical ecological value, and management decisions should prioritize conservation, transparency, and long-term population recovery. To ensure the survival of horseshoe crabs, much better management plans and more sustainable practices are desperately needed as soon as possible.

It is beyond time for Massachusetts to join New York and Connectcut in conserving horseshoe crabs rather than intensifying their exploitation.

Thank you for your attention to this critical matter and for considering my comments.

Sincerely,
Helen Lozoraitis

Dan McKiernan
Director, Massachusetts Division of Marine Fisheries

Dear Director McKiernan,

I am writing as a Massachusetts resident to comment on the Division of Marine Fisheries' current proposal to change horseshoe crab quotas.
Myself and my family care a lot about wildlife and animals in general. We have long been upset by the obvious decline of horseshoe crabs on our beaches. Horseshoe crabs are ancient animals surviving millions and millions of years and we are decimating them. And for no good reason.
There are other bait possibilities, obviously, and there are synthetic options for the medical uses. Please see all the well organized points below with links to more information as well.
But the main point is that we see no excuse for further horseshoe crab exploitation.
Please stop it all!!!

Given that DMF's own proposal acknowledges declining bait demand while expanding the number of horseshoe crabs used for biomedical purposes, and that horseshoe crabs have not fully recovered statewide, this is an appropriate moment to end the use of horseshoe crabs for bait and maintain (or LOWER) the existing 200,000 biomedical quota, rather than expand overall harvest pressure. This is how other coastal states are behaving and let's not lag behind in a world of exploitation for no reason.

Horseshoe crabs are a public trust resource with critical ecological value, and management decisions should prioritize conservation, transparency, and long-term population recovery. Please end the use of horseshoe crab for bait and lower or end entirely the existing biomedical quota.

Please see further detailed points below and thank you for your careful attention to our concerns.

Sincerely, Sarah Stewart and Family
85 Garfield Street
Watertown, MA 02472

1. **Horseshoe Crabs Are a Public Trust Resource—** Horseshoe crabs are a public trust resource, not a private commodity. Management should prioritize the public interest, ecosystem health, and long-term sustainability—not private commercial convenience.
2. **Horseshoe Crabs Are a Keystone Species**— Horseshoe crabs are a keystone species, supporting migratory shorebirds, fisheries productivity, and coastal ecosystem health. Their decline impacts the coastal food web, harming wildlife and fisheries alike. Protecting horseshoe crabs directly advances Governor Healey's biodiversity order by safeguarding a species essential to ecosystem resilience and food-web stability.
3. **Removing Crabs from Spawning Beaches Undermines Reproduction—** When a horseshoe crab is removed from a spawning beach before it spawns, there is no guarantee it will successfully reproduce, even if it is later returned during the same spawning season. Disrupting spawning undermines population recovery.
4. **Massachusetts Should End the Use of Horseshoe Crabs—** Massachusetts should end the use of horseshoe crabs for bait. Horseshoe crabs are far too ecologically and medically valuable to be killed for a depleted whelk fishery. Ending the bait fishery would immediately reduce overall mortality, simplify management, and allow the Commonwealth to focus on recovery and conservation.
5. **DMF's Proposal Expands Exploitation Instead of Reducing It—** The proposed management changes convert bait quota into biomedical take through the Rent-A-Crab program. Rather than reducing pressure on horseshoe crabs, this proposal expands exploitation at a time when conservation should be the priority.
6. **Biomedical Quota Increase—** In 2023, the Massachusetts Division of Marine Fisheries capped the biomedical horseshoe crab quota at 200,000 and split that quota evenly between the two existing processors. Now, DMF is proposing to raise the biomedical quota to 280,000 crabs, plus routing an additional 100,000 bait crabs through the rent-a-crab program. to the bleeding facilities. Ask why!
7. **Horseshoe Crabs Belong to the Public—** These animals are a public resource, not a private supply. Management decisions should prioritize long-term conservation and healthy coastal ecosystems—not expand access for private companies.
8. **Cruelty to Animals—** Some believe horseshoe crabs are incapable of feeling pain, even after repeated bleeding where needles pierce their hearts and 1/3 of their blood is drained. Animal rights organizations such as Humane World for Animals and Doctors

Against Animal Experiments disagree.

9. **Lack of Transparency Limits Public Oversight—** The so-called “rule of three,” derived from G.L. c. 130, §21, prevents disclosure of fisheries data unless at least three reporting entities are involved. Under the statute, such reports are held “strictly confidential by the director and shall not be disclosed except in compliance with a valid court order.” This policy limits transparency, obscures the true scale and impacts of horseshoe crab harvest and prevents meaningful public oversight of management decisions involving a public resource. We need to ask DMF to evaluate this non-public data as if horseshoe crab recovery were the first priority—and to explain how current harvest levels are consistent with conservation and the Commonwealth’s public trust responsibilities.
10. **Massachusetts Is Falling Behind Neighboring States—** Neighboring states are moving away from horseshoe crab exploitation. New York and Connecticut have taken stronger conservation action. Massachusetts should follow their lead and conserve horseshoe crabs before further declines become irreversible.
11. **There Is a Better Way—** As highlighted by The Boston Globe (Feb. 10, 2026), Massachusetts wants to bleed more horseshoe crabs. What if there was a better way. " Massachusetts is moving backward.”" **Synthetic alternatives exist, bait demand is declining, and conservation-first management is achievable—if Massachusetts chooses to lead rather than lag behind."**

8. **Cruelty to Animals—** Some believe horseshoe crabs are incapable of feeling pain, even after repeated bleeding where needles pierce their hearts and 1/3 of their blood is drained. Animal rights organizations such as Humane World for Animals and Doctors Against Animal Experiments disagree.
9. **Lack of Transparency Limits Public Oversight—** The so-called "rule of three," derived from G.L. c. 130, §21, prevents disclosure of fisheries data unless at least three reporting entities are involved. Under the statute, such reports are held "strictly confidential by the director and shall not be disclosed except in compliance with a valid court order." This policy limits transparency, obscures the true scale and impacts of horseshoe crab harvest and prevents meaningful public oversight of management decisions involving a public resource. We need to ask DMF to evaluate this non-public data as if horseshoe crab recovery were the first priority—and to explain how current harvest levels are consistent with conservation and the Commonwealth's public trust responsibilities.
10. **Massachusetts Is Falling Behind Neighboring States—** Neighboring states are moving away from horseshoe crab exploitation. New York and Connecticut have taken stronger conservation action. Massachusetts should follow their lead and conserve horseshoe crabs before further declines become irreversible.
11. **There Is a Better Way—** As highlighted by The Boston Globe (Feb. 10, 2026), Massachusetts wants to bleed more horseshoe crabs. What if there was a better way. " Massachusetts is moving backward."" **Synthetic alternatives exist, bait demand is declining, and conservation-first management is achievable—if Massachusetts chooses to lead rather than lag behind."**

Attention: Dan McKiernan, Director, Massachusetts Division of Marine Fisheries

Dear Director McKiernan,

I am writing as a Massachusetts resident to comment on the Division of Marine Fisheries' current proposal to change horseshoe crab quotas.

Given that DMF's own proposal acknowledges declining bait demand while expanding the number of horseshoe crabs used for biomedical purposes, and that horseshoe crabs have not fully recovered statewide, **this is an appropriate moment to end the use of horseshoe crabs for bait and maintain the existing 200,000 biomedical quota, rather than expand overall harvest pressure**.

Horseshoe crabs are a public trust resource with critical ecological value, and management decisions should prioritize conservation, transparency, and long-term population recovery.

Thank you for considering my comments.

Dear Director McKiernan,

I am writing as a Massachusetts resident, Conservation Agent, and former employee of a major producer of limulus amebocyte lysate to comment on the Division of Marine Fisheries' current proposal to change horseshoe crab quotas.

Given that DMF's own proposal acknowledges declining bait demand while expanding the number of horseshoe crabs used for biomedical purposes, and that horseshoe crabs have not fully recovered statewide, **this is an appropriate moment to end the use of horseshoe crabs for bait and maintain the existing 200,000 biomedical quota, rather than expand overall harvest pressure**. From my experience in the field I know that crabs harvested are often supplied by fishers, so having separate quotas for bait and biomedical use only complicates the issue of conservation. I also know there are viable alternatives to horseshoe crab amebocytes for the production of LAL on the horizon, but until they've passed the vigorous FDA testing required, horseshoe crab populations will continue to suffer.

Horseshoe crabs are a public trust resource with critical ecological value, and management decisions should prioritize conservation, transparency, and long-term population recovery.

Thank you for considering my comments.

Sincerely,
Joe Jerolimo

Attention: Dan McKiernan, Director, Massachusetts Division of Marine Fisheries

Dear Director McKiernan,

I have lived on the Cape for most of my life. I married into a Cape Cod family and we spend a lot of time in Cape Cod Bay and in Pleasant bay, walking and kayaking. It is evident from years spent on the water that there are fewer and fewer horseshoe crabs.

I am writing as a Massachusetts resident to comment on the Division of Marine Fisheries' current proposal to change horseshoe crab quotas.

Given that DMF's own proposal acknowledges declining bait demand while expanding the number of horseshoe crabs used for biomedical purposes, and that horseshoe crabs have not fully recovered statewide, **this is an appropriate moment to end the use of horseshoe crabs for bait and maintain the existing 200,000 biomedical quota, rather than expand overall harvest pressure**.

Horseshoe crabs are a public trust resource with critical ecological value, and management decisions should prioritize conservation, transparency, and long-term population recovery.

Dan McKiernan
Director, Massachusetts Division of Marine Fisheries

Dear Director McKiernan,

I am writing as a Massachusetts resident to comment on the Division of Marine Fisheries' current proposal regarding horseshoe crab quotas.

The DMF's own proposal acknowledges declining bait demand while expanding the number of crabs used for biomedical purposes. Given that horseshoe crabs have not fully recovered statewide, I believe this is the appropriate time to end the use of horseshoe crabs for bait and maintain the existing 200,000 biomedical quota, rather than increasing overall harvest pressure.

Massachusetts should join neighboring states like Connecticut and New York in recognizing the decreased need for bait and the irreplaceable role horseshoe crabs play in our stressed ecosystem. Prioritizing the conservation of this public resource over its commodification is essential. I urge the DMF to take an ethical, long-term view by supporting synthetic alternatives to biomedical bleeding.

Horseshoe crabs are a public trust resource with critical ecological value. Management decisions should prioritize conservation, transparency, and long-term population recovery. With synthetic alternatives available and bait demand declining, Massachusetts has the opportunity to lead in conservation-first management.

Thank you for considering my comments.

Sincerely,
Suzanne McLeod

CAUTION: This email originated from a sender outside of the Commonwealth of Massachusetts mail system. Do not click on links or open attachments unless you recognize the sender and know the content is safe.

Dear Director McKiernan,

We see that the Division of Marine Fisheries' proposal to change horseshoe crab quotas recognizes shrinking demand for bait along with increasing use of horseshoe crabs for biomedical applications, and that horseshoe crab populations remain low across the Commonwealth.

By DMF's own reckoning, Massachusetts needs to stop using horseshoe crabs for bait, and safeguard the current 200,000 needed for biomedical uses. There are no circumstances to justify increasing harvesting at this time.

As a public good of enormous environmental consequence, horseshoe crabs call for transparent public policies that put protection first.

Thank you for considering my comments.

Attention: Dan McKiernan, Director, Massachusetts Division of Marine Fisheries

Dear Director McKiernan,

I am writing as a Massachusetts resident to comment on the Division of Marine Fisheries' current proposal to change horseshoe crab quotas.

Given that DMF's own proposal acknowledges declining bait demand while expanding the number of horseshoe crabs used for biomedical purposes, and that horseshoe crabs have not fully recovered statewide, **this is an appropriate moment to end the use of horseshoe crabs for bait and maintain or reduce the existing 200,000 biomedical quota, rather than expand overall harvest pressure**. The bait usage is akin to throwing these beings into the trash heap, and the biomedical use is simply a money grab, largely benefiting private companies and equity firms, NOT the public at large. There is a high level of mortality with current practices, and effort should be taken to reduce that mortality rate by investigating different and more effective fluid extraction procedures.

Horseshoe crabs are a public trust resource with critical ecological value, and management decisions should prioritize conservation, transparency, and long-term population recovery.

Thank you for considering my comments.

Attention: Dan McKiernan, Director, Massachusetts Division of Marine Fisheries

Dear Director McKiernan,

I am writing as a Massachusetts resident to comment on the Division of Marine Fisheries' current proposal to change horseshoe crab quotas.

I understand that DMF's own proposal acknowledges that there is declining demand for horseshoe crab bait. Since the horseshoe crab population has not fully recovered statewide, **this is an appropriate moment to end the use of horseshoe crabs for bait.** Maintaining the number of horseshoe crabs used for biomedical purposes, should be a priority so I strongly recommend **maintaining the existing 200,000 biomedical quota, rather than expanding the overall harvest pressure**.

Horseshoe crabs are a public trust resource with critical ecological value, and management decisions should prioritize conservation, transparency, and long-term population recovery.

Thank you for considering my comments.

Dear Director McKiernan,

I am writing as a Massachusetts resident and educator to comment on the Division of Marine Fisheries' current proposal to change horseshoe crab quotas. I teach 300 high school students in my Oceanography course a year. I include a unit on horseshoe crabs. Every year my students are shocked that there are as many horseshoe crabs that are allowed to be harvested and allowed to be bled given the low population numbers and the many environmental obstacles these ancient animals are impacted by. The students understand these animals are a keystone species and our fisheries depend on them, migratory birds depend on them and marine food webs need them to be healthy.

Given that DMF's own proposal acknowledges declining bait demand while expanding the number of horseshoe crabs used for biomedical purposes, and that horseshoe crabs have not fully recovered statewide, **this is an appropriate moment to end the use of horseshoe crabs for bait and maintain the existing 200,000 biomedical quota, rather than expand overall harvest pressure**.

We ask you to include more oversight of how horseshoe crabs are treated/handled when brought to the bleeding facility. There can be more care given to these valuable animals and more monitoring to insure better care.

Horseshoe crabs are a public trust resource with critical ecological value, and management decisions should prioritize conservation, transparency, and long-term population recovery.

Thank you for considering my comments.

Attention: Dan McKiernan, Director, Massachusetts Division of Marine Fisheries

Dear Director McKiernan,

I am writing as a Massachusetts summer resident to comment on the Division of Marine Fisheries' current proposal to change horseshoe crab quotas.

NOAA Fisheries has denied Endangered Species Act protection for the horseshoe crab. Even though environmental groups are suing to try change this decision, it appears that it is up to the States to protect our marine resources.

DMF indicates that the horseshoe crab population has not recovered statewide. It seems inadvisable to set overall quotas higher than the current quotas. Please **end the use of horseshoe crabs for bait and maintain the existing 200,000 biomedical quota, rather than expand overall harvest pressure**.

Horseshoe crabs are a public trust resource with critical ecological value, and management decisions should prioritize conservation, transparency, and long-term population recovery.

Dear Director McKiernan,

I grew up in Gloucester, Massachusetts, combing beaches and tide pools with my brothers. It was a rare but precious moment whenever we found a horseshoe crab--I think we instinctively understood and respected their ancient lineage. I'm writing now to comment on the Division of Marine Fisheries' current proposal to change horseshoe crab quotas.

Given that DMF's own proposal acknowledges declining bait demand while expanding the number of horseshoe crabs used for biomedical purposes, and that horseshoe crabs have not fully recovered statewide, **this is an appropriate moment to end the use of horseshoe crabs for bait and maintain the existing 200,000 biomedical quota, rather than expand overall harvest pressure**.

Horseshoe crabs are a public trust resource with critical ecological value, and management decisions should prioritize conservation, transparency, and long-term population recovery.

Though I live primarily in Michigan now, I visit Massachusetts regularly and still care deeply about its maring creatures. thank you for considering my comments and those of so many current residents of Massachusetts.

Sincerely,
Susan B. Whitlock
Ann Arbor, MI 48105

Attention: Dan McKiernan, Director, Massachusetts Division of Marine Fisheries

Dear Director McKiernan,

I am writing as a Cape Cod resident to comment on the Division of Marine Fisheries' current proposal to change horseshoe crab quotas.

Horseshoe crabs are a public trust resource with critical ecological value, and management decisions should prioritize conservation, transparency, and long-term population recovery.

Horseshoe crabs are important in coastal ecosystems:

- Their eggs are a critical food source for migratory shorebirds, including the threatened red knot.
- They are slow to mature, taking 11 years to reach reproductive size, making them highly vulnerable to overharvesting.
- Horseshoe crabs play an important role in the coastal food web, supporting several commercially valuable fish.

Given that DMF's own proposal acknowledges declining bait demand while expanding the number of horseshoe crabs used for biomedical purposes, and that horseshoe crabs have not fully recovered statewide, **this is an appropriate moment to end the use of horseshoe crabs for bait and maintain the existing 200,000 biomedical quota, rather than expand overall harvest pressure**.

This is a critical moment for us to expand environmental protections, not reduce them. I consider myself a part of a Cape Cod community that is not exclusive to the humans who inhabit this beautiful area, but inherently includes all of the creatures who reside here.

Thank you for considering my comments.

Sincerely,
K.E. Schrieber
Falmouth, MA

Attention: Dan McKiernan, Director, Massachusetts Division of Marine Fisheries

Dear Director McKiernan,

I am writing as a Massachusetts resident to comment on the Division of Marine Fisheries' (DMF) current proposal to adjust horseshoe crab quotas.

Given that the DMF proposal acknowledges declining bait demand while simultaneously expanding the number of horseshoe crabs used for biomedical purposes—and considering that populations have not fully recovered statewide—I believe this is the appropriate time to end the use of horseshoe crabs for bait. Furthermore, I urge the Division to maintain the existing 200,000 biomedical quota rather than increasing overall harvest pressure.

Horseshoe crabs are a public trust resource with critical ecological value. Management decisions should prioritize conservation, transparency, and long-term population recovery.

Thank you for your time and for considering my comments.

Dear Director McKiernan,

I am writing as a Massachusetts resident to comment on the Division of Marine Fisheries' current proposal to change horseshoe crab quotas.

Given that DMF's own proposal acknowledges declining bait demand while expanding the number of horseshoe crabs used for biomedical purposes, and that horseshoe crabs have not fully recovered statewide, **this is an appropriate moment to end the use of horseshoe crabs for bait and maintain the existing 200,000 biomedical quota, rather than expand overall harvest pressure**.

Horseshoe crabs are a public trust resource with critical ecological value, and management decisions should prioritize conservation, transparency, and long-term population recovery.

Thank you for considering my comments.

Sincerely,
Mary Wong-Sommer

Dear Director McKiernan,

I am writing as a Massachusetts resident to comment on the Division of Marine Fisheries' current proposal to change horseshoe crab quotas.

Given that DMF's own proposal acknowledges declining bait demand while expanding the number of horseshoe crabs used for biomedical purposes, and that horseshoe crabs have not fully recovered statewide, **this is an appropriate moment to end the use of horseshoe crabs for bait and maintain the existing 200,000 biomedical quota, rather than expand overall harvest pressure**. I'm not even sure why the biomedical quota needs to be included as there is a synthetic version of this compound now available.

Horseshoe crabs are a public trust resource with critical ecological value, and management decisions should prioritize conservation, transparency, and long-term population recovery. I grew up on West Bay in Osterville, and as a child I remember seeing horseshoe crabs all the time but now it's a rare site. Until there is a clearer picture of the health of the population, harvesting should be reduced.

Thank you for considering my comments.

Sincerely,

Dear Director McKiernan,

I am writing as a Massachusetts resident to provide comments on the Division of Marine Fisheries' proposed changes to horseshoe crab quotas.
Given that the proposal itself notes a decline in bait demand, alongside an increase in horseshoe crabs allocated for biomedical use, and considering that statewide populations have not yet fully recovered, this is an appropriate moment to end the use of horseshoe crabs for bait. Maintaining the existing biomedical quota of 200,000-rather than expanding overall harvest pressure-would better support long-term sustainability.
Horseshoe crabs are a public trust resource with significant ecological importance, and management decisions should reflect a commitment to conservation, transparency, and the recovery of healthy populations.

Thank you for your consideration.

Dear Director McKiernan,

I live on Cape Cod and am writing as a Massachusetts resident to comment on the Division of Marine Fisheries' current proposal to change horseshoe crab quotas.

I believe that since DMF's own proposal recognizes declining demand for bait while increasing the number of horseshoe crabs allocated for biomedical use—and given that statewide populations have not fully recovered—this is the right time to end the use of horseshoe crabs for bait and keep the current 200,000-crab biomedical quota in place (frankly, I'd rather it were reduced), rather than increasing overall harvest pressure.

Horseshoe crabs are sentient beings with critical ecological value, and management decisions should prioritize conservation, transparency, and long-term population recovery. And, it is the right thing to do.

Thank you for considering my comments.

Dear Director McKiernan,

I am as Massachusetts resident issuing my comments on the Division of Marine Fisheries' current proposal to change horseshoe crab quotas.

Your own DMF's proposal acknowledges declining bait demand while expanding the number of horseshoe crabs used for biomedical purposes. You acknowledge that horseshoe crabs - a KEYSTONE species in the ecosystem - have not fully recovered all along the East Coast and beyond.

This is an appropriate moment to end the use of horseshoe crabs for bait and maintain the existing 200,000 biomedical quota, rather than expand overall harvest pressure. Harvest pressure affects and endangers this and any species survival.

Shorebirds, shoreline life forms, and the environment expect you to make the informed decision: leave Horseshoe Crabs alone.

Protect horseshoe crabs - February 2026

To: dan.mckiernan@mass.gov

Dear Mass DMF,

I can't believe how special, extractive/consumptive uses dominant our natural resources here even in supposedly "liberal" Massachusetts. There have been many attempts to better protect horseshoe crabs and now you want to allow more "harvest' of them all while other states are banning the harvest of them. Wake up and protect horseshoe crabs for the following reasons.

1. **Horseshoe Crabs Are a Public Trust Resource—** Horseshoe crabs are a public trust resource, not a private commodity. Management should prioritize the public interest, ecosystem health, and long-term sustainability—not private commercial convenience.
2. **Horseshoe Crabs Are a Keystone Species**— Horseshoe crabs are a keystone species, supporting migratory shorebirds, fisheries productivity, and coastal ecosystem health. Their decline impacts the coastal food web, harming wildlife and fisheries alike. Protecting horseshoe crabs directly advances Governor Healey's biodiversity order by safeguarding a species essential to ecosystem resilience and food-web stability.
3. **Removing Crabs from Spawning Beaches Undermines Reproduction—** When a horseshoe crab is removed from a spawning beach before it spawns, there is no

guarantee it will successfully reproduce, even if it is later returned during the same spawning season. Disrupting spawning undermines population recovery.

4. **Massachusetts Should End the Use of Horseshoe Crabs—** Massachusetts should end the use of horseshoe crabs for bait. Horseshoe crabs are far too ecologically and medically valuable to be killed for a depleted whelk fishery. Ending the bait fishery would immediately reduce overall mortality, simplify management, and allow the Commonwealth to focus on recovery and conservation.
5. **DMF's Proposal Expands Exploitation Instead of Reducing It—** The proposed management changes convert bait quota into biomedical take through the Rent-A-Crab program. Rather than reducing pressure on horseshoe crabs, this proposal expands exploitation at a time when conservation should be the priority.
6. **Biomedical Quota Increase—** In 2023, the Massachusetts Division of Marine Fisheries capped the biomedical horseshoe crab quota at 200,000 and split that quota evenly between the two existing processors. Now, DMF is proposing to raise the biomedical quota to 280,000 crabs, plus routing an additional 100,000 bait crabs through the rent-a-crab program to the bleeding facilities. Why?
7. **Horseshoe Crabs Belong to the Public—** These animals are a public resource, not a private supply. Management decisions should prioritize long-term conservation and healthy coastal ecosystems—not expand access for private companies.
8. **Cruelty to Animals—** Some believe horseshoe crabs are incapable of feeling pain, even after repeated bleeding where needles pierce their hearts and 1/3 of their blood is drained. Animal rights organizations such as Humane World for Animals and Doctors Against Animal Experiments disagree.
9. **Lack of Transparency Limits Public Oversight—** The so-called "rule of three," derived from G.L. c. 130, §21, prevents disclosure of fisheries data unless at least three reporting entities are involved. Under the statute, such reports are held "strictly confidential by the director and shall not be disclosed except in compliance with a valid court order." This policy limits transparency, obscures the true scale and impacts of horseshoe crab harvest and prevents meaningful public oversight of management decisions involving a public resource. We need to ask DMF to evaluate this non-public data as if horseshoe crab recovery were the first priority—and to explain how current harvest levels are consistent with conservation and the Commonwealth's public trust responsibilities. These laws sound more like Trump policy with no accountability; this doesn't even remotely involve any science which your organization is supposed to follow.
10. **Massachusetts Is Falling Behind Neighboring States—** Neighboring states are moving away from horseshoe crab exploitation. New York and Connecticut have taken stronger conservation action. Massachusetts should follow their lead and conserve horseshoe crabs before further declines become irreversible. It is inexcusable that you

are trending the opposite direction of this trend. Inexcusable!

11. **There Is a Better Way—** As highlighted by The Boston Globe (Feb. 10, 2026), Massachusetts wants to bleed more horseshoe crabs. What if there was a better way. " Massachusetts is moving backward."" **Synthetic alternatives exist, bait demand is declining, and conservation-first management is achievable—if Massachusetts chooses to lead rather than lag behind.**

Just like MassWildlife's hell-bent approach to allowing hunting as much as they can to a minority of people, consider the vast majority of people who do not kill these crabs and who would rather conserve them.

Regards,

Jonathan Way

I am writing to express my concern with Massachussetts exploitation of horseshoe crabs. Growing up on Long Island, I spent much of my childhood on the shores of long island where these crabs were a welcomed and abundant presence - a keystone species. I never imagined that they would become a commodity, laid claim to for use in medical research and bait. These crabs are not for private sale. They belong to the public and have their own intrinsic value. Massachusetts needs to immediately severely limit and move rapidly to ultimately ban the exploitation of horseshoe crabs.

The ongoing exploitation of this species is unsustainable and unforgivable!

Dear Director McKiernan,

I am writing as a Massachusetts resident who cares deeply about the health of our coastal ecosystems and the humane treatment of wildlife. I am very concerned about the Division of Marine Fisheries' proposal to change horseshoe crab quotas.

Your own proposal notes that bait demand is declining, yet it would allow for expanded biomedical use at a time when horseshoe crab populations have not fully recovered statewide. This feels like the wrong direction. Rather than increasing overall harvest pressure, I urge DMF to end the use of horseshoe crabs for bait and maintain the current 200,000 biomedical quota.

Beyond the ecological impact, I am troubled by the suffering involved. Horseshoe crabs used for bait are captured, handled, and killed in large numbers, and even those used for biomedical purposes undergo stressful bleeding procedures. These are ancient, remarkable animals that play a vital role in coastal food webs, particularly for migratory shorebirds. Expanding harvest at this point does not reflect careful stewardship of a public trust resource.

Management decisions should prioritize conservation, transparency, humane considerations,

and long-term population recovery over short-term industry interests.

Thank you for your time and for considering my comments.

Sincerely,

Ann Cilfone

Dan McKiernan
Director, Massachusetts Division of Marine Fisheries

Dear Director McKiernan,

I am writing as a scientist and concerned Massachusetts resident.

Horseshoe crabs are a public trust resource and a keystone species essential to coastal ecosystem function. Their eggs support migratory shorebirds, and their ecological role contributes to fisheries productivity and biodiversity. Population declines therefore have cascading food-web and conservation impacts.

Current management practices undermine recovery. Removal of crabs from spawning beaches prior to reproduction disrupts spawning success, and proposed changes by the Division of Marine Fisheries would increase, rather than reduce, exploitation. These include expansion of biomedical harvest quotas (from 200,000 to 280,000 crabs) and additional routing of bait crabs through the Rent-A-Crab program. Such measures warrant clear justification within a conservation framework.

Given the species' ecological and biomedical importance, continued use as bait in a depleted whelk fishery is difficult to justify. Ending the bait fishery would reduce mortality and support

recovery. Concerns also remain regarding animal welfare impacts of biomedical bleeding practices.

Finally, limited transparency in fisheries data constrains independent evaluation of harvest impacts. Conservation-first management — consistent with actions in neighboring states and enabled by emerging synthetic alternatives — represents a scientifically supportable path forward.

Massachusetts has the opportunity — and responsibility — to align with regional conservation leadership and implement stronger protections now.

Sincerely,

Heidi Hutton

Subject: Proposed Revisions to Horseshoe Crab Quotas
Date: Monday, February 16, 2026 6:24:36 PM

CAUTION: This email originated from a sender outside of the Commonwealth of Massachusetts mail system. Do not click on links or open attachments unless you recognize the sender and know the content is safe.

Dear Director Dan McKiernan,

I am writing as a Massachusetts resident to comment on the Division of Marine Fisheries' current proposal to change horseshoe crab quotas.

Given that DMF's own proposal acknowledges declining bait demand while expanding the number of horseshoe crabs used for biomedical purposes, and that horseshoe crabs have not fully recovered statewide, this is an appropriate moment to end the use of horseshoe crabs for bait and maintain the existing 200,000 biomedical quota, rather than expand overall harvest pressure.

More specifically:

1. **Horseshoe Crabs Are a Public Trust Resource—** Horseshoe crabs are a public trust resource, not a private commodity. Management should prioritize the public interest, ecosystem health, and long-term sustainability—not private commercial convenience.
2. **Horseshoe Crabs Are a Keystone Species**— Horseshoe crabs are a keystone species, supporting migratory shorebirds, fisheries productivity, and coastal ecosystem health. Their decline impacts the coastal food web, harming wildlife and fisheries alike. Protecting horseshoe crabs directly advances Governor Healey's biodiversity order by safeguarding a species essential to ecosystem resilience and food-web stability.
3. **Removing Crabs from Spawning Beaches Undermines Reproduction —** When a horseshoe crab is removed from a spawning beach before it spawns, there is no guarantee it will successfully reproduce, even if it is later returned during the same spawning season. Disrupting spawning undermines population recovery.
4. **Massachusetts Should End the Use of Horseshoe Crabs—** Massachusetts should end the use of horseshoe crabs for bait. Horseshoe crabs are far too ecologically and medically valuable to be killed for a depleted whelk fishery. Ending the bait fishery would immediately reduce overall mortality, simplify management, and allow the Commonwealth to focus on recovery and conservation.
5. **DMF's Proposal Expands Exploitation Instead of Reducing It—** The proposed management changes convert bait quota into biomedical take through the Rent-A-Crab program. Rather than reducing pressure on horseshoe crabs, this proposal expands exploitation at a time when conservation should be the priority.

Horseshoe crabs are a public trust resource with critical ecological value, and management decisions should prioritize conservation, transparency, and long-term population recovery.

Thank you for considering my comments.

Sincerely,
Peter Crawley

Given that DMF's own proposal acknowledges declining bait demand while expanding the number of horseshoe crabs used for biomedical purposes, and that horseshoe crabs have not fully recovered statewide, this is an appropriate moment to end the use of horseshoe crabs for bait and maintain the existing 200,000 biomedical quota, rather than expand overall harvest pressure.

Horseshoe crabs are a public trust resource with critical ecological value, and management decisions should prioritize conservation, transparency, and long-term population recovery.

Horseshoe crabs are not a private commodity. Management should prioritize the public interest, ecosystem health, and long-term sustainability—not private commercial convenience.

Horseshoe crabs are a keystone species, supporting migratory shorebirds, fisheries productivity, and coastal ecosystem health. Their decline impacts the coastal food web, harming wildlife and fisheries alike. Protecting horseshoe crabs directly advances Governor Healey's biodiversity order by safeguarding a species essential to ecosystem resilience and food-web stability.

When a horseshoe crab is removed from a spawning beach before it spawns, there is no guarantee it will successfully reproduce, even if it is later returned during the same spawning season. Disrupting spawning undermines population recovery.

Neighboring states are moving away from horseshoe crab exploitation. New York and Connecticut have taken stronger conservation action. I am very surprised and disappointed Massachusetts has not. Massachusetts should follow their lead and conserve horseshoe crabs before further declines become irreversible.

Thank you for considering my comments.

Best Regards,

Linda Holland

American Bird Conservancy

Bold action for birds across the Americas

Director Daniel J. McKiernan
Division of Marine Fisheries
marine.fish@mass.gov
March 4, 2026

Re: Proposal on Horseshoe Crab Quota Reallocation

Dear Director McKiernan,

American Bird Conservancy (ABC) appreciates the opportunity to comment on the horseshoe crab quota reallocation proposal put forth by the Division of Marine Fisheries (DMF). The American horseshoe crab needs greater conservation efforts; however, we believe DMF's proposal to reallocate horseshoe crab bait quota to the biomedical sector will not advance this objective. **We are therefore in opposition to the proposal and urge DMF to consider ending the bait harvest entirely—an action that would conserve crabs and benefit other wildlife.**

ABC is a nonprofit organization dedicated to the conservation of wild birds and their habitats across the Americas, including in Massachusetts. We take on the greatest challenges facing birds. The decline in horseshoe crabs and their eggs across the Atlantic Coast poses a threat to shorebirds reliant upon the eggs for their migratory journeys.

One of the shorebirds most impacted by a lack of horseshoe crabs is the rufa Red Knot. This robin-sized bird is a champion long-distance flyer, traveling more than 9,000 miles one way during migration. In 2014, the Red Knot was listed as threatened under the Federal Endangered Species Act. The listing petition, along with the subsequent recovery plan, emphasize how integral horseshoe crab eggs are to the survival of Red Knot. Overharvest of the horseshoe crab in the mid-20th century, including in Massachusetts, fueled declines in the horseshoe crab and Red Knot populations. Along with being federally listed, the Red Knot is listed as threatened under the Massachusetts Endangered Species Act (MESA).

DMF states in the proposal that overall horseshoe crab mortality would be reduced by "about 28,000 crabs annually, assuming a 15% biomedical mortality rate." Following this, DMF says that the estimated bait need for this fishery is "in the range of 75,000 to 90,000 horseshoe crabs annually." These figures are lower than the existing (140,000) or proposed (100,000) bait quotas. DMF recognizes that "Massachusetts routinely approaches fully utilizing its horseshoe crab bait quota…because biomedical demand for these crabs—through the rent-a-crab program—is driving bait harvest." Reassigning the bait quota to biomedical does not offer a real-world reduction in mortality or meaningfully address the underlying conservation needs.

Synthetic alternatives to test the safety of medical therapies exist and can replace the use of the Limulus Amebocyte Lysate (LAL)—which is made from horseshoe crab blood. Last year, the US Pharmacopeia recognized synthetic methods as equivalent, and the US Congress advanced a provision instructing the Food and Drug Administration (FDA) to update its 2012 endotoxin testing guidance to accept synthetic

methods. Once the guidance is updated, it could further accelerate adoption of synthetic methods and reduce the need for biomedical harvest.

Given the conservation needs of the Red Knot and horseshoe crab, and the growing use of synthetic methods in medical safety testing, we urge you to forgo this proposal. Instead, we encourage you to act in the interest of conservation by banning the bait harvest of horseshoe crabs.

Thank you for considering our comments and your attention to this issue.

Sincerely,

American Bird Conservancy

On a personal note:

Dan McKiernan
Director, Massachusetts Division of Marine Fisheries 3-3-2026

Dear Director McKiernan,
This is my second letter to you, the other on 2-24-26.
I have been a resident of Cape Cod for over fifty years and the author of several books for children about misunderstood animals and those of special concern. Dr. Carl Schuster
was my mentor for many years, and his wisdom about horseshoe crabs was invaluable to me. In turn, he asked me for feedback from a 'non-scientist's' reading of his not yet published 'The American Horseshoe Crab.' He helped me with his advice to raise an approximately 2 cm horseshoe crab until its 10th year much to the amazement of us both. A male, dying he thought, as it tried to transition to its adult claspers.

Around 1990, I began observing diminishing numbers of horseshoe crabs on beaches that were once teeming with spawning crabs. This continued for several years, prompting me to contact several conservation groups to express concern and letters to Paul Diodati in 2000, then Director of Marine Fisheries in Massachusetts who was polite. I wrote several articles (as an observer) to the Cape Codder and the Cape Cod Times, and the responses expressed observations Cape-wide of diminishing numbers as well. I provided workshops and programs about the horseshoe crab for The New England Aquarium, Atlantic Marine Center, Wellfleet Bay Audubon and Cape Cod classrooms. Yes, I was just an observer…not a scientist nor an official conservationist. But time passed. I researched and studied harvesting trends, joined the numerous HSC conservation groups, did spawning surveys, attended many MDMF meetings. In my own observer opinion, I have been a long time witness to what I believe has been a basic disregard of the DMF for the long-term survival of this ancient species. Others at this second DMF hearing, continuing the HSC Fishery quota update, will outline (yet again and again and again) the essential reasons for disapproving this most recent proposal.

I have written to you a number of times on similar issues concerning horseshoe crab conservation. For years, in fact, as well as attending many hearings and meetings where we both were present along with fishermen, biomedical company representatives, conservation groups and the general public. Evidently, the subject never gets old. Perhaps not old, but in my opinion for so many years no really efficacious measures taken for effective conservation of the horseshoe crab in MA, especially in the Cape Cod area.

Horseshoe crabs are a public trust resource, not a private commodity. DMF's proposal expands exploitation instead of reducing it. The lack of transparency of the so-called 'rule of three' limits public oversight (and has that 'who are you kidding?' aspect. And more. So much more. Observers were right all along.

Thank you for listening,
Carol Amato

From: Carol Amato
To: McKiernan, Dan (FWE)
Subject: DMF Public Hearing re Horseshoe Crab Quotas from Carol A. Amato
Date: Sunday, February 22, 2026 3:31:25 PM
Attachments: Dan McKiernan 2026 .doc

CAUTION: This email originated from a sender outside of the Commonwealth of Massachusetts mail system. Do not click on links or open attachments unless you recognize the sender and know the content is safe.

I will include text of this letter.

Dan McKiernan
Director, Massachusetts Division of Marine Fisheries 2-22-2026

Dear Director McKiernan,
I am writing as a Massachusetts resident to comment on the Division of Marine Fisheries'current proposal to change horseshoe crab quotas.

Given that DMF's own proposal acknowledges declining bait demand while expanding the number of horseshoe crabs used for biomedical purposes, and that horseshoe crabs have not fully recovered statewide, this is an appropriate moment to end the use of horseshoe crabs for bait and maintain the existing 200,000 biomedical quota, rather than expand overall harvest pressure.

Horseshoe crabs are a public trust resource with critical ecological value, and management decisions should prioritize conservation, transparency, and long-term population recovery.

On a personal note:

I have written to you a number of times on similar issues concerning horseshoe crab conservation. For years, in fact, as well as attending many hearings and meetings where we both were present along with fishermen, biomedical company representatives, conservation groups and the general public. Evidently, the subject never gets old. Perhaps not old but in my opinion and under your DMF leadership, for many years most disappointing measures that do not favor effective conservation for the horseshoe crab in MA, especially in the Cape Cod area.

With your new quotas for harvesting up and coming, I could present so many reasons why this is more of the same disregard for the survival of the species…but you've heard all these opinions before. I will re-emphasize:
DMF's proposal would deliver 80,000 more crabs for bleeding under the biomedical permit. And, Under the rent-a-crab program—unique to Massachusetts—most, if not all, bait-designated crabs would be routed to biomedical companies for bleeding before they are sold for bait adding an additional 100,000 to the biomedical total.

This management decision comes at a time when bait demand is declining due to the collapse of the whelk fishery, and biomedical companies are increasingly transitioning to a synthetic alternative to horseshoe crab blood. Rather than using this moment to reduce pressure and rebuild horseshoe crab populations statewide, DMF's proposal moves in the opposite direction—prioritizing private commercial interests over long-term population recovery, ecosystem health, and resilience.

Mr. McKiernan, really!
What has changed to justify allowing biomedical companies to bleed up to 380,000 horseshoe crabs?

And ultimately, what is driving this decision—science and conservation, or private industry interests?

Whose crabs are these, anyway?

Massachusetts is likely to face increased regional pressure following the passage of legislation in New York ending the use of horseshoe crabs for both bait and biomedical purposes—potentially increasing industry demand toward the Commonwealth. Continued harvesting at these levels undermines long-term population recovery, ecosystem function, and the Commonwealth's public trust responsibilities.

It is time for Massachusetts to join New York and Connecticut in conserving horseshoe crabs rather than intensifying their exploitation.

Thank you for listening.

Re: Comments on the Massachusetts Division of Marine Fisheries Draft Horseshoe Crab Quotas for 2026

Dear Director McKiernan,

The Association to Preserve Cape Cod (APCC) writes with strong concern regarding the Division of Marine Fisheries' (DMF) proposal to reduce the 2026 horseshoe crab bait quota from 140,000 to 100,000 horseshoe crabs and increase the biomedical quota from 200,000 to 280,000. We respectfully ask the DMF to reconsider and revise this proposal.

Founded in 1968, APCC is the Cape region's leading nonprofit environmental advocacy and education organization, working for the adoption of laws, policies and programs that protect, preserve and restore Cape Cod's natural resources. APCC focuses our efforts on the protection of groundwater, surface water, and wetland resources, preservation of open space, the promotion of responsible, planned growth and the achievement of an environmental ethic.

Horseshoe crabs are a fascinating and ancient species that play a critical role in coastal ecosystems. Their eggs are a vital food source for local and migratory shorebirds, as well as for many other important marine species. Their unique blood has also been used for endotoxin testing to ensures the safety of medical products and vaccines.

Despite their scientific and ecological importance, horseshoe crab populations have plummeted to dangerously low levels in recent decades due in part to commercial bait harvesting for the whelk and eel fisheries. This decline of the horseshoe crab population has significant consequences for the entire ecosystem, including many commercially important fish and shellfish species. Your own agency has classified the whelk fishery as "depleted and overfished, with overfishing continuing." DMF data also suggests that demand for bait crabs from whelk harvesters is below 100,000 animals per year. Other advantageous bait sources exist, such as the invasive green crab, which are abundant in Massachusetts waters and which have adversely impacted the shellfish industry.

Given that DMF's own quota proposal acknowledges declining bait demand while expanding the number of horseshoe crabs used for biomedical purposes, and that horseshoe crabs have not fully recovered statewide, this is an appropriate moment to end the use of horseshoe crabs for bait.

In addition, recognizing that synthetic alternatives to horseshoe crab blood now exist for biomedical use, we recommend that DMF consider decreasing the biomedical quota below the 2025 level of 200,000 and certainly not increase it to 280,000.

The time to wind down the exploitation of horseshoe crabs has come and the DMF proposal is an insufficient response to a complex situation.

On behalf of APCC, thank you for considering these comments and suggestions.

Sincerely,

Andrew Gottlieb
Executive Director

Re: Horseshoe Crab Quota Reallocation Proposal

Dear Director McKiernan:

Thank you for the opportunity to comment on the proposed horseshoe crab quota reallocation. Mass Audubon **supports** the proposed changes to the DMF regulations for horseshoe crabs. Reallocating a portion of the quota from the bait fishery to the biomedical harvest makes sense as the demand for bait has decreased and this reallocation will result in an incremental reduction in overall mortality for horseshoe crabs. More broadly, Mass Audubon recommends that DMF establish a goal, pursuant to the Biodiversity Initiative under Executive Order 618, for recovery of the population along the Massachusetts coast for the species' important ecological role as a food source for migratory shorebirds. Phasing out both the bait fishery and the biomedical harvest should be planned, though we recognize that this will take time, particularly for the biomedical industry. More information is needed on the proposed 1:2 reallocation from bait to biomedical, given that many companies are already making the transition to synthetics (see pharmascore.org.).

We feel this proposal is a reasonable next step to take following the 2024 decision to close both fisheries for a period in the spring to protect spawning horseshoe crabs. Mass Audubon appreciates the attention and effort that DMF applies to this species, recognizing its significant ecological role. We also appreciate the ongoing partnership with DMF as Mass Audubon coordinates monitoring at many sites and provides data utilized by DMF in tracking population trends.

Horseshoe Crabs' Ecological Role

As you know, horseshoe crabs have important ecological connections to declining and federally protected shorebirds in Massachusetts. Horseshoe crab eggs are a key food source for the Rufa Red Knot, federally and state-listed as a threatened species, as well as other long-distance migratory shorebirds. Massachusetts was historically part of the network of spring stopover sites for Red Knots, with numbers up to 25,000 recorded in eastern Cape Cod Bay in the 19th century, and records showing over 5,000 spring knots as recently as 1953 at Monomoy, all likely feeding on crab eggs.

Even now, over the past few years, shorebird researchers have observed hundreds of Red Knots and thousands of other shorebirds at Monomoy, many feeding on horseshoe crab eggs in sandbars. The hatchling larvae may also provide food for southbound migrating birds into late summer. Improved food sources increase the chances for shorebirds to survive long-distance migration in a condition leading to successful reproduction. We are partnering with others in the region to continue to collect data, so that DMF can make sound science-based policy in the future.

Horseshoe crabs play many other important roles in the ecosystem. Their eggs and hatched larvae provide food for fish, and the adults are eaten by sharks and the federally threatened loggerhead sea

turtle. They prey on polychaete worms and other marine invertebrates, and stir up benthos with their burrowing, providing nutrition for bottom-dwelling organisms, and helping to sustain the benthic food chain.

DMF's monitoring data indicate that the horseshoe crab population in Massachusetts is generally stable or slowly increasing. However, these data need to be considered within the context of historic natural populations, which were evidently orders of magnitude higher. While the historic reports are not in a form that enables rigorous scientific analysis, the historic record is still robust enough to confirm that the current population levels are greatly diminished.

Mass Audubon's Role in Protecting Horseshoe Crabs

For over two decades, Mass Audubon has sought improved management of horseshoe crabs and restoration of the population. In addition to our advocacy efforts, which included rallying public support for the 2024 spawning closure, we support horseshoe crab management by training volunteer monitors and providing DMF with spawning survey data. Through this work, we have developed a deep network of advocates and members who care about the iconic species. Mass Audubon is committed to continuing this work in partnership with DMF and other organizations and individuals.

Planning for a Bright Future for Horseshoe Crabs

While we appreciate this step forward, we urge DMF to continue to work with both fisheries to further minimize impacts to horseshoe crabs. DMF should establish a long-term goal of restoring horseshoe crab populations in Massachusetts to once again achieve healthy spawning densities that support feeding shorebirds up and down Massachusetts coasts.

Protecting and restoring the horseshoe crabs of Massachusetts may indeed be a more significant piece of the puzzle to species recovery of threatened and endangered shorebirds than previously thought. Shorebird populations are rapidly declining in North America, with some species losing more than 90% of their population in the past four decades (Smith et al. 2023, *Ornithological Applications*). Given the recent evidence of Red Knots and other declining bird species feeding on horseshoe crab eggs at Monomoy National Wildlife Refuge, it is important to maintain and increase this food source to increase the chances of successful shorebird migration, survival, and reproduction.

Horseshoe crabs and the ecosystems they support are also struggling with habitat loss, as coastal development, erosion, and sea level rise present increasing threats to beaches, salt marshes, and other coastal habitats. This context is important to consider, in relation to Executive Order 618 and the Massachusetts Biodiversity Goals. Management of this linchpin species should be consistent with those conservation goals.

DMF's Proposal for Quota Reallocation

Mass Audubon's advocacy surrounding horseshoe crabs prioritizes a focus on reducing mortality. DMF's proposed quota reallocation embraces that approach by reducing the allowable catch by nearly 30% for the bait fishery, an industry in which *every* animal that is caught dies. This is why our top near-term priority is phasing out the bait fishery.

The proposed reallocation also decreases the reliance of the biomedical harvest on bait catch. Assuming a mortality rate of 15%, the proposed increase in the biomedical quota of 80,000 will result in the loss of

approximately 12,000 animals, still providing a net gain for the population through the 40,000 animals that will be saved through the bait harvest quota reduction.

We do have questions about the basis for a 1:2 ratio in the reallocation and ask DMF to reconsider whether this is appropriate and necessary. The biomedical industry is beginning to transition to synthetic alternatives to lysate derived from horseshoe crab blood. We would appreciate an opportunity to learn what information supports this increase in demand.

Conclusion

Mass Audubon supports reallocation of horseshoe crab quotas from the bait fishery to the biomedical fishery as a step toward the larger goal of restoring a more robust horseshoe crab population. We look forward to continued dialogue and partnership with DMF staff and leadership as we come together around a shared vision for restoring the horseshoe crab's role in marine and coastal ecosystems. We appreciate the progress demonstrated through this current proposal. We hope it is adopted and that DMF continues to invest in a sustainable future for horseshoe crabs in Massachusetts.

Appreciatively,

E. Heidi Ricci
Director of Policy and Advocacy

Director Dan McKiernan

February 9, 2026

Re: Horseshoe Crab Quota

Thank you for being responsive to those of us who are lobbying for the conservation of horseshoe crabs. We commend you on the recent changes made to the seasonal restrictions on harvest of horseshoe crabs.

I write in opposition to the recent proposal to change quotas. The decrease in bait harvest of 40,000 horseshoe crabs makes sense given the declining whelk fishery. I **oppose** the increase of 80,000 horseshoe crabs for biomedical purposes. This proposed increase promotes the additional use of a public resource for the benefit of private companies. Furthermore, the proposed increase does **nothing to encourage biomedical companies to use the new and approved molecular technologies that replace LAL.** Horseshoe crabs are no longer needed.

Proposing increased total quotas seems premature, given that we don't know if the existing seasonal closures are working to maintain the current horseshoe crab populations. It will take years to find out. As a compromise measure, I would suggest using the 40,000 horseshoe crab bait quota reduction and apportioning 20,000 to each of the two biomedical companies.

-Barbara Brennessel, Ph.D.

Wellfleet, MA

February 27, 2026

Daniel McKiernan, Director
Massachusetts Division of Marine Fisheries

Dear Director McKiernan and Members of the Division of Marine Fisheries,

I am writing to formally oppose the proposed 2026 changes to horseshoe crab quota management. While I appreciate the Division's effort to revisit the bait quota, the overall proposal increases biomedical exploitation and fails to prioritize long term conservation of a public trust species that plays a critical role in Massachusetts coastal ecosystems.

The proposal reduces the bait quota from 140,000 to 100,000 crabs but increases the biomedical quota from 200,000 to 280,000. Under the Rent A Crab program, bait designated crabs may also be routed to biomedical facilities for bleeding prior to being sold for bait. This means that up to 380,000 horseshoe crabs could be bled annually.

This represents a significant expansion of exploitation at a time when bait demand is declining and synthetic biomedical alternatives are increasingly viable. DMF's own proposal acknowledges that annual bait demand approximates 75,000 to 90,000 crabs. Setting a bait quota above actual need, while simultaneously increasing biomedical take, does not reflect precautionary or conservation focused management.

Horseshoe crabs are a public trust resource and a keystone species. Their eggs support migratory shorebirds and contribute to the broader productivity and stability of coastal ecosystems. Removing crabs from spawning beaches disrupts reproduction and undermines population recovery. When a spawning female is taken before she lays eggs, there is no guarantee she will successfully spawn later in the season. These biological realities must guide management decisions.

The biomedical industry has access to a scientifically validated alternative to horseshoe crab blood. Recombinant Factor C, or rFC, is a synthetic reagent used for endotoxin detection in medical products. Numerous peer reviewed studies have demonstrated that rFC is as sensitive and reliable as traditional limulus amebocyte lysate testing derived from horseshoe crab blood. rFC eliminates dependence on wild harvested animals and reduces ecological pressure.

The United States Pharmacopeia has formally recognized synthetic endotoxin testing methods as acceptable alternatives. Major pharmaceutical companies have already begun transitioning portions of their testing to rFC. Continued expansion of biomedical quotas suggests that Massachusetts is accommodating industry inertia rather than encouraging innovation and sustainability.

Voluntary transition is often slow without legislative direction. If Massachusetts is serious about conservation, it should support policies that require or strongly incentivize a shift toward rFC and away from wild harvested horseshoe crabs. Industry adoption will accelerate when there is a clear regulatory signal that reliance on live bleeding is not the long term path forward.

There are also viable alternatives for bait. Research conducted in the Northeast has demonstrated that invasive green crab can be used effectively as bait for whelk. Studies have shown that combinations of green crab and surf clam attract whelk at rates comparable to horseshoe crab bait in controlled trials. Using invasive green crab as bait would reduce pressure on horseshoe crabs while supporting ecological management goals.

At a time when the whelk fishery is struggling and bait demand is declining, this is an opportunity to reduce harvest pressure and invest in alternative bait research and implementation. Instead, the

proposed quota framework maintains or increases overall take.

Neighboring states have taken stronger conservation steps. Massachusetts should not position itself as a refuge for expanded industry extraction in response to regional conservation efforts.

I respectfully urge the Division to reconsider the proposed biomedical quota increase, reevaluate the bait quota in light of actual demand, and prioritize a management framework that advances population recovery, ecosystem health, and transparency. Horseshoe crabs belong to the public. Management decisions should reflect long term ecological stewardship rather than short term commercial accommodation.

Thank you for your time and consideration.

Sincerely,

Joe Castro
Boston & Provincetown, Massachusetts

THE PROGRAM FOR PRESERVING THE NATURAL WORLD, INC.

March 5, 2026

The Massachusetts Division of Marine Fisheries (DMF) proposes raising the biomedical quota of the American horseshoe crab (*Limulus polyphemus*) from 200,000 to 280,000 while, lowering the bait quota from 140,000 to 100,000. Yet, because bait crabs may be bled first under the "rent-a-crab" program, as many as 380,000 could be subject to bleeding, not including crabs transported into Massachusetts from other states.

Few scientists examining the available data would conclude that *L. polyphemus* in Massachusetts is thriving. Surveys cited as evidence of stability began only after populations had already declined sharply from historic levels. A population far below its former abundance cannot reasonably be described as recovered.

Horseshoe crabs play a critical ecological role. Their eggs—and the crabs themselves—are essential food for many species, including migratory shorebirds such as the red knot, federally listed as threatened under the U.S. Endangered Species Act, and the loggerhead sea turtle, also listed as threatened. When horseshoe crab populations decline, species that depend on them decline as well.

Two commercial enterprises threaten horseshoe crab recovery: fisheries using them as bait and biomedical companies bleeding them to produce Limulus amoebocyte lysate (LAL), used to detect bacterial toxins in vaccines and medical devices. While LAL is lifesaving, effective synthetic alternatives now exist and are increasingly used by pharmaceutical companies. Maintaining firm limits on the biomedical harvest would help accelerate the transition while protecting a species already under ecological pressure.

With the strongest commitment to biodiversity conservation in the nation, Massachusetts should honor that commitment by ending the use of horseshoe crabs as bait and maintaining the current biomedical cap during the transition to synthetic alternatives. If we fail to act, we risk contributing to the decline of a species that has survived for more than 400 million years—an avoidable tragedy.

These opinions are mine, and mine alone, and do not necessarily reflect those of anyone connected to The Program for Preserving the Natural World, Inc.

Re: Comments on MA DMF's Horseshoe Crab Management Proposal

Conservation Law Foundation appreciates the opportunity to comment on this important issue and your Proposal on Horseshoe Crab Management. [1] In the bait fishery, we support the proposed 40,000 crab decrease in this action but urge MA DMF to work with fishermen on bait alternatives that would allow this fishery to be phased out. We do not support the proposed 80,000 crab increase in the biomedical sector. There are alternatives already in use by Eli Lilly and other pharmaceutical companies, and any increase in quota incentivizes the pharmaceutical industry to delay necessary research that would secure FDA approval of alternatives.

For the long-term health of horseshoe crabs and the marine ecosystem, CLF proposes MA DMF move towards prohibiting harvest for all purposes. Horseshoe crabs are integral to ecosystems in the Commonwealth as part of the food web.[2] Adults and their eggs provide food for migratory birds, such as the red knot and Hudsonian godwit, as well as threatened and endangered species such as endangered loggerhead sea turtles.[3] At least nine valuable commercial fish species, including Winter flounder and swordfish, prey on horseshoe crabs.[4] Horseshoe crabs could play an even larger role in our environment if the population increases and they become a reliable and abundant food source.

Historically, the residents of the Commonwealth used horseshoe crabs in many ways that put pressure on the species including for use as fertilizer, bait for the whelk and eel fisheries, and as a source of Limulus amebocyte lysate (LAL) for the biomedical industry.[5] Local municipalities considered horseshoe crabs to be a threat to certain shellfish (including soft

shelled clams), leading them to set bounties for crabs up until 1970.[6] As a result of the many historical uses, since the 1950s, hundreds of thousands of horseshoe crabs die each year.[7]

In 1997, the Atlantic States Marine Fisheries Commission (ASMFC) began regulating horseshoe crabs following concerns that the species faced over-exploitation, but due to a lack of data they could not establish biological reference points to define when the species is "overfished" or experiencing "overfishing." Those definitions still do not exist today.[8] The ASMFC measures recovery by comparing today's population size to its size in 1998, the first year of management.[9] This means that the index-based reference point for managing recovery centers on a population size determined after decades of removal of hundreds of thousands of crabs each year. Despite this low benchmark, a large share of surveys in the Northeast, 34-65%, indicate that the population is more likely than not still below the 1998 level.[10] Horseshoe crabs have not recovered to the reduced abundance level of 1998, let alone the population size that existed before decades of exploitation.

Horseshoe crabs also face threats to recovery due to climate change. The species is experiencing a loss of spawning and nursery areas due to extreme weather, sea level rise, and coastal development.[11] Climate change will only increase those risks as severe weather events become more frequent and sea level rise accelerates.[12] With threats to horseshoe crabs growing, now is not the time to increase the horseshoe crab harvest quota. Instead, CLF supports MA DMF beginning to phase out the horseshoe crab harvest.

Harvest of Horseshoe Crabs as Bait Should be Phased Out as Soon as Possible

While MA DMF's Notice proposes to reallocate 40,000 crabs from the bait quota such that it would decrease from 140,000 to 100,00, the bait quota is still too large.[13] If MA DMF continues to allow the harvest of horseshoe crabs as bait, CLF urges it to prioritize working with the conch pot fishery to test and facilitate a transition to bait alternatives that eliminates the burden of the bait quota on horseshoe crabs.[14]

There are more sustainable alternatives to using horseshoe crabs as bait. In Massachusetts, horseshoe crabs are largely used as bait in the conch pot fishery which is already concerning because whelk are "depleted" throughout Massachusetts and "overfished and subject to overfishing" in the Nantucket Sound.[15] It is also unnecessary as studies show whelk find bait mixtures consisting of surf or propeller clams and green crabs are just as or more attractive than mixtures using horseshoe crabs.[16] Green crabs are an especially good bait alternative because they are an invasive species with a detrimental impact on eelgrass, coastal marsh health, and native bivalves.[17] A survey of the whelk fishery in Massachusetts shows that the majority of respondents already use some form of a bait mixture, including mixtures with green crab.[18] However, respondents overwhelmingly still use horseshoe crab in those mixtures, even though studies show it is not necessary.[19]

CLF urges MA DMF to go farther than the proposed decrease in the bait quota and commit to transitioning to bait alternatives that will allow phasing out the use of horseshoe crabs as bait entirely. In the immediate short-term, MA DMF can minimize the burden of the bait harvest by extending spawning protections through July starting this summer. Data shows horseshoe crabs in Massachusetts historically spawn well into July and August.[20] Ending the spawning closure by the beginning of June interferes with the historic spawning period, impeding recovery.

Harvest of Horseshoe Crabs for the Biomedical Sector Should be Phased Out as Soon as Possible

CLF does not support an increase to biomedical quota of 80,000 horseshoe crabs as MA DMF proposes.[21] There is no need to permit—let alone increase—the harvest of horseshoe crabs

for biomedical use as non-animal derived alternatives can replace reliance on LAL from horseshoe crab blood.

The U.S. Pharmacopeia Microbiology Expert Committee, which includes eight U.S. Food and Drug Administration representatives, authorized non-animal derived reagents for use in endotoxin testing in 2024.[22] Even before that, starting in 2018, the FDA began approving drugs that relied on those alternative endotoxin processes.[23] Alternative endotoxin testing reagents are already in use by several large pharmaceutical businesses including Eli Lilly and Company, which has two Boston-based facilities.[24] Non-animal derived reagents are sufficiently available and reliable such that CLF supports eliminating the biomedical quota for horseshoe crabs to allow the species to recover.

Any quota increase is a step in the wrong direction. MA DMF originally set the cap at 200,000 in 2023 and it is too soon to increase that cap especially based only on demand from the biomedical industry. As Atlantic coastal states ban harvest—which New York has just done—demand will increase on Massachusetts stocks.[25] The biomedical industry already has access to all the bait quota horseshoe crabs through the Rent-a-Crab program, meaning they use well over the 200,000 crabs allotted to biomedical purposes.

MA DMF's proposal to use a new 1:2 reallocation ratio instead of the previously used 1:6 ratio is a step in the right direction, but it is not enough.[26] The ratio is applied when moving crabs from the bait quota, where crabs have 100% mortality rate, to the biomedical quota, where crabs are estimated to have between a 15-30% mortality rate.[27] The proposed ratio attempts to more appropriately incorporate the sublethal effect of bleeding in management decisions; however, the

lack of data on the mortality of released crabs makes the reallocation ratio an unreliable tool for management.[28] CLF does not support reallocation of horseshoe crabs to the biomedical quota because reallocation does not appropriately consider the burden of biomedical harvest on horseshoe crab recovery.

To safeguard the long-term health of our marine ecosystem, CLF supports the decrease of 40,000 crabs in the bait fishery, but it does not support the 80,000-crab increase in the biomedical sector. Eventually, we would like to see harvesting phased out. As an important part of our ecosystems, horseshoe crabs sustain critical predator-prey relationships, their eggs provide an irreplaceable food source for threatened migratory birds, and with viable non-animal derived alternatives available for medical testing, there is no longer a justification for exploiting a species that has stabilized our coastal waters for over 450 million years.

Thank you for consideration of our comments.

Subject: Recapping My comments on the Proposed Horseshoe Crab Catch Limits
Date: Friday, March 6, 2026 4:22:48 PM

CAUTION: This email originated from a sender outside of the Commonwealth of Massachusetts mail system. Do not click on links or open attachments unless you recognize the sender and know the content is safe.

Hi Dan:

I wanted to recap my comments more succinctly from the public comment call the other day.

The State of Massachusetts should be reducing the allowable catch limits for both bait *and* biomedical purposes to move toward an eventual ban like New York State. There is not an infinite supply of horseshoe crabs.

Birds that eat horseshoe crab eggs: Red Knots, Dunlin, Sanderling, Laughing Gulls. Semi-palmated Plovers, Ruddy Turnstones. All of these birds are in decline. We know horseshoe crabs are a critical food source. Even lobsters and other crustaceans eat horseshoe crab eggs. Horseshoe crab eggs are key to whole ecosystems in the ocean. Lobster populations are struggling as well. With climate change, all of the above species are under stress. Thus, making horseshoe crab eggs more plentiful can potentially help these species sustain their numbers.

When there are synthetic solutions available to industry, making LAL from horseshoe crabs more accessible to that industry does not help their Big Pharma's long-term purchasing power. Demand shifts and the companies making synthetic LAL may opt to get out of the business. In fact, the State should want more companies manufacturing synthetic LAL. This is the long-term solution. Having worked in the biopharma industry for many years, I can tell you that pharmaceutical companies can afford to buy synthetic LAL.

Please consider a weaning approach where harvests on the bait and biomedical go down year over year. If NY can do it, I would think MA can do it as well.

Thank you.

Regards,

Emily Ross

Dear Director McKiernan,

I am writing to you as a Massachusetts resident and taxpayer opposed to the proposed horseshoe crab quota changes.

I have lived on the island of Martha's Vineyard since the spring of 1992, working as a coastal biologist focused on wildlife research, monitoring, and conservation. One of my first experiences with horseshoe crabs was marveling at the abundant food resource their eggs provided for migratory shorebirds in Katama bay. That same spring I followed a truck from the edge of Katama bay on Chappaquiddick island to the Chappaquiddick ferry and observed 10 different horseshoe crabs falling out of a fisherman's truck bed as he made that trip because he had piled them too high in his truck bed. He showed little regard for these amazing animals and their role in the ecosystem, not even noticing they were falling off of his truck as he drove down the road. He likely thought, as many did and do, that they were an abundant resource that would never disappear. I stopped to pick up those crabs and released those that were salvageable. I later learned these crabs would be ground up to be used as bait for the whelk fishery and that the harvested whelk meat would then be shipped all the way to Asia. Over a hundred thousand crabs were being harvested not to feed people here in Massachusetts but to ship to Asia.

As the whelk fishery is now collapsing, it is surprising that the Division of Marine Fisheries is proposing to permit more horseshoe crab harvest for bait that the fishery needs. In addition, you are proposing to increase the harvest for biomedical use. Nearby states have already banned the take of horseshoe crabs for bait. It is time for Massachusetts to end the bait take too.

I do not support increasing the current biomedical cap either. Maintain it as it is and prioritize ecological recovery. Your management should be grounded in sound science and restoration rather than expanded exploitation of this species.

Thank you for your time and consideration.

CAUTION: This email originated from a sender outside of the Commonwealth of Massachusetts mail system. Do not click on links or open attachments unless you recognize the sender and know the content is safe.

Dear Director McKiernan,

I am writing in support of bill H. 898: An Act to End the Taking of Horseshoe Crabs for Bait. I am a lifelong nature enthusiast and horseshoe crab fan, and have read numerous books and news articles about the manmade challenges these ancient and critically important animals face. The combined toll of habitat loss, bait take, and exploitation by the pharmaceutical industry impacts not just horseshoe crabs, but all of the other species that rely on them. This bill will help to address the pressures that horseshoe crabs face and would be an important first step towards prioritizing ecological recovery.

Dan McKiernan
Director, Massachusetts Division of Marine Fisheries
Dear Director McKiernan,
I am writing as a concerned Massachusetts resident to comment on the Division of Marine Fisheries' current proposal to change crab quotas. Horseshoe crabs were once an abundant resource in Massachusetts waters. Sadly until recently, they have been a very poorly managed resource, with numbers severely declining. I attended the recent zoom meeting that requested public comments. Listed below are my thoughts:
I am deeply against your proposal to actually increase harvest totals when the resource is in very early stages of minimal recovery. I was shocked to learn that only 1% of our state's horseshoe crab population exists north of Cape Cod. They were once a very plentiful resource here and bounties were actually offered to remove them. As a conversationalist, I have always believed in conservation first, before harvesting of a resource is allowed. A sensible and moral plan for any resource should always take this approach! It is my sincere hope that fishermen have a sustainable fishery with proper conservation guidelines and by taking corrective action for resources that have been depleted.
New York and Connecticut have already taken the progressive approach to ban horseshoe crab harvesting. With Massachusetts also being a progressive state, we should follow their lead and preserve this ancient resource that been such an important part of our ecology. With the whelk fishery declining and other bait alternatives, bait harvesting should be phased out. There are humane synthetic biomedical alternatives to replace the cruel blood draining approach now being used. I find it very hard to believe that only a 15% mortality rate occurs for a crab drained of 1/3 it its blood.
I have been to Monomoy Wildlife Refuge and Morris Island numerous times and seen what a thriving eco-system looks like with their presence. It is my sincere hope that horseshoe crabs can rebound if give a proper chance in other parts of Massachusetts. They have existed for an estimated 450 million years, making them a living fossil.
Sincerely,
Bill Vickstrom

Thank you David those are good comments.

We need to reimagine the fishery to fit these times, and recognize the varied services provided by what we sometimes regard as stocks or independent bank accounts. These are actually highly dynamic and interdependent as are the species and interactions that give rise to them. This is inconsistent with the concept of maximum sustainable yield unless "yield" includes all values- both those that derive from dead fishes, and those that derive from live fishes. The "live" is still taken for granted as simply what is out there prior to its deading. There is little thought about the *minimum level of a species for ecosystem sustainability,* or the overall demand profiles put out there by both the market and non-market economies.

Subject: Comment on Last Night's Massa. Division of Fisheries Management Public Hearing on Proposed Regulations

Dear Director Dan McKierran

I didn’t have the time to comment on the horseshoe crab proposal to reduce the commercial catch quota

and increase the medical catch for this iconic species which has been in the ocean, since the dinosaurs
walked on land. On Cape Cod and the Islands, we have lost our working water front to tourism and other non-marine activities, so that the commercial whelk fishery utilizing horseshoe crab bait has less economic contribution to our economy than tourists/residents who celebrate female horseshoe crab
breeding on our beaches.

Extreme weather events (blizzards; tornadoes and hurricanes) are more
common which leads to beach erosion and more sand bars offshore or beach expansion elsewhere (Seee recent Association for the Preservation of Cape Cod Newsletter piece by Andrew Gottlieb). During a recent drive along Surf Drive in Falmouth following the recent blizzard, I observed a diminished beach and dredge out in the ocean removing sand in the channel. This is bound to effect the Essential Fish Habitat for horseshoe crabs which is not being considered by the Massa. Division of Marine Fisheries. When I participated in the "Productive Capacity of Wetlands" project in Louisiana,
oil/gas drilling increased saltmarsh erosion from canals which diminished offshore shrimp production.
Coastal eelgrass beds and onshore saltmarshes/sand dunes on Cape Cod help reduce beach erosion.

Discharge of treated sewage effluent in coastal water (3 million gallons per day for Falmouth) will increase
nutrients (nitrogen and phosphorus); toxic chemicals (PFAS, heavy metals and microplastics) and microbes
which could Impact horseshoe crabs and other commercial fish and shellfish populations. Thus Massa. DMF
should adapt an adaptive, ecosystems-based fisheries management approach (see 2021 comments from
Sierra Club to Massa. Coastal Zone Management for revision of Massachusetts Ocean Management Plan).
The MOMP 2026 revision process appears to leave the effects of climate change on finfish and shellfish
up to the Massa. Division of Marine Fisheries. The MOMP revision webinar included numerous elected
officials from Cape Cod and Islands where the horseshoe crab fishery is conducted. MOMP and the Coastal Biodiversity initiative should be integrated into the Massa. DMF management process.

When I earned my Ph.D. in Zoology from the University of Georgia in 1971, I studied under Gene Odum
(Ecosystem Ecologist) and Larry Pomeroy (Biological Oceanographer), who emphasized looking at the big
picture in converting science into government policies/regulations. I retired from NOAA Fisheries Northeast
Fisheries Science Center- Woods Hole Laboratory in 2009 and was quite disappointed that the presentations
in last nights public hearing didn't exhibit shifts made in recent years (climate change effects by Mid-Atlantic
Fishery Management Council; ecological economics estimates on values of natural capital and ecosystem
Services; Environmental Justice and Diversity/Equity/Inclusion constituent challenges; increasing biodiversity and ecosystem services restoration; environmental stressors from human economic exploitation
in the ocean and creating a sustainable economy as human populations increase). Hopefully the

Hello Director McKiernan,

I would like to submit a comment in support of the proposal to decrease the bait harvest quota by 40,000 and increase the biomedical harvest quota by 80,000.

I intentionally refer to the biomedical quota as a **harvest**, because that is the most scientifically accurate description. These animals are removed from the ocean, handled, and subjected to bleeding procedures that cause significant physiological stress. Your department has stated that approximately **one in six animals dies as a result of this process**. While five of six are returned to the water, they do not return unchanged. Many experience reduced survival and diminished ability to function normally for an extended period of time. So while I don't support raising the amount of harvesting any horseshoe crabs at this time, shifting the harvest to save 28,000 horseshoe crabs is better than nothing.

Despite the public comments from well-intentioned fishermen, the scientific consensus is clear: **Red Knots depend heavily on horseshoe crab eggs**. During their migration from South America along the eastern seaboard, these birds concentrate in areas where horseshoe crab spawning occurs because they must rapidly accumulate fat reserves. Without sufficient food, many birds fail to complete their migration or arrive on their breeding grounds in poor condition, which can prevent successful reproduction. This has direct and serious consequences for the long-term health of the species.

I understand that it may feel outside the traditional scope of a Division of Marine Fisheries to consider the needs of migratory shorebirds. However, managing a resource like horseshoe crabs cannot be done in isolation. Horseshoe crabs occupy a critical role in a broader ecological system. Tens of thousands of migratory birds rely on the timing and abundance of their spawning events. Effective fisheries management therefore requires an **ecosystem-level perspective**, not a single-species approach.

It is also important to acknowledge the economic structure of this fishery. Virtually every horseshoe crab harvested for bait is first bled by LAL manufacturers. In practice, the entire horseshoe crab fishery functions as a supply chain supporting companies such as ACC and Charles River. Much of the revenue fishermen receive is ultimately tied to the biomedical industry rather than to the bait market itself. This dynamic helps explain why there is currently a surplus of bait crabs that have already been captured and bled.

There are also clear **economic benefits to increasing the number of spawning horseshoe crabs**.

First, larger spawning populations support healthier populations of migratory shorebirds such as Red Knots. These birds attract thousands of birdwatchers, photographers, and naturalists each year who travel to coastal areas specifically to witness the migration. Bird tourism generates significant economic activity for local communities through lodging, restaurants,

guiding services, and related tourism.

Second, horseshoe crab spawning events themselves have become a major wildlife attraction. People travel to coastal areas specifically to observe these ancient animals coming ashore in large numbers. A larger spawning population increases the reliability and scale of this spectacle, creating additional opportunities for educational programs, guided experiences, and coastal tourism.

Third, increasing the spawning population contributes to the overall health of the coastal ecosystem. Horseshoe crabs play an important role in supporting biodiversity, and a healthy ecosystem benefits many marine species that regional fisheries depend on. Protecting this biodiversity helps maintain the productivity and stability of coastal waters, which ultimately supports the long-term success of commercial and recreational fisheries.

For these reasons, the decision before you is not simply about allocating crabs between bait and biomedical uses. It is also about the broader ecological and economic consequences of harvest levels and the responsibility to manage this resource in a way that supports the health of the entire ecosystem, including the migratory shorebirds that depend on horseshoe crab spawning.

Thank you for your time and consideration.

Director Dan McKiernan,

I am a resident of Brighton, Massachusetts and a medical student at Boston University. I am writing regarding the Division of Marine Fisheries' plans for horseshoe crab quotas.

I have seen the majestic horseshoe crab only once in person while visiting Martha's Vineyard in the summer. Horseshoe crabs are sentient creatures that can feel pain. Their blood is not needed for biomedical purposes because there is a synthetic alternative, recombinant Factor C (rFC). Please end the use of horseshoe crabs for both bait and biomedical uses. In my view, zero horseshoe crabs should be harmed for either of these purposes.

Horseshoe crabs are ancient, predating dinosaurs. However, their numbers have fallen precipitously. Since horseshoe crabs are keystone organisms, their declining numbers are felt throughout Massachusetts's ecosystem. New York, New Jersey, and Connecticut have banned or substantially restricted horseshoe crab harvests. Please guard Massachusetts rich biodiversity and natural splendour for future generations and choose kindness by ending the killing and bleeding of horseshoe crabs.

Best regards,
Nakul Vyas

Good Evening,

My name is Cole Dobratz and I am a twenty one year old full time commercial fisherman from Old Lyme, Connecticut. Growing up here, I was blessed to have spent many childhood years learning the industry from both my grandfather, and father, making myself a proud third generation waterman. If I wasn't helping commercially, you would have likely found younger me running around our local beaches, docks, and marshes. As a result of this upbringing, I developed an understanding and appreciation for our delicately balanced ecosystem.

Within the past few years, I have watched the state of Connecticut take away the commercial horseshoe crab industry without a fight. Having owned just one of 12 standing HSC licenses prior to the ban on harvesting, us few fishermen simply had no chance. Although we did not have a voice against much larger environmentalist groups boasting thousands of members, I believe Massachusetts' watermen have the chance to prove what we could not; That the horseshoe crabs populations along the east coast are more plentiful than ever.

If these harvesting reductions are passed, I believe the fisherman will never again see this quota returned. In Connecticut, we first saw lunar closures and catch reductions. In just a few years, it was shut down completely. Today, fishermen are now fighting a ban to make using horsecarbs or their eggs for bait completely illegal in our state. We are dealing with a death from 1,000 cuts, that I believe could financially ruin my lifelong dream and passion. If this ban occurs in my and your state, I will no longer be able to afford to catch conch and eels, and therefore my business will likely not succeed.

I hope that you will consider the viewpoints and data displayed by your fisherman to draw the best conclusions before going forward with any drastic measures. Take it from your neighbor, who has seen the cascading effects of regulation in just a few short years.

Best,
Cole Dobratz

Dear Director McKiernan,

As a MA resident, I remember going to Horse Neck Beach in the 1970s and seeing hundreds of horseshoe crabs. Now, I'm lucky if I see one. Please significantly reduce the harvest quotas like other states have. Let the population recover back to its norm.

I'm reading that bait demand is declining due to the collapse of the whelk fishery, and pharmaceutical companies are increasingly transitioning to a synthetic alternative to horseshoe crab blood as highlighted by The Boston Globe (Feb. 10, 2026), Massachusetts wants to bleed more horseshoe crabs. What if there was a better way. " Massachusetts is moving backward."" Synthetic alternatives exist, bait demand is declining, and conservation-first management is achievable—if Massachusetts chooses to lead rather than lag behind." It's horrible that they pierce their hearts, drain their blood and put them back in the ocean. I've seen documentation that there is a 30% mortality rate but it is speculated that the mortality rate is higher since some of them that are put back in the ocean still do not survive.

Horseshoe crabs have been around Massachusetts for millions of years. Let's keep this iconic species around for millions more.

Thank you.

Best,

Hello! My name is Judy Asarkof. As a Mass resident, I am asking you to PLEASE end the bait take, maintain or even decrease the taking of horseshoe crabs for biomedical use, and PLEASE prioritize their recovery. Human use has decimated the populations and frankly, that is very concerning.

I remember as a kid seeing so many in the Cape Cod Bay area!!! and around Massachusetts seeing all the horseshoe crabs leading their lives. It is horrendous that I see so few these days! It is time to stop our use and abuse of sensitive species and horseshoe crabs need to recover!

Thank you!

Hello Dan McKiernan and colleagues,

As a former fisheries biologist for NOAA with a scientific publication on horseshoe crab research, I support the total phasing out of horseshoe crabs being harvested for bait and eventually for bleeding, as well, in MA. I write to you as a private citizen, since I was illegally fired from my career of 19 years by some kid named Big Balls who worked for trillionaire Musk's DOGE for a hot minute last year.

It sounds like there is a compromise happening with the bait and biomedical harvest. I would support eliminating the bait harvest entirely and using bled crabs doubly to satisfy the bait demand, while eventually bait usage of HSCs is phased out as well. There are plenty of synthetic and alternate baits to use. We don't need to remove more HSCs than absolutely "necessary".

Horseshoe crabs are an ancient species that requires laying eggs on land to reproduce. These eggs are an essential part of the diet of migratory birds each year, including the threatened Red Knot. HSCs are an essential part of the coastal ecosystem, and we must not only protect their population from overharvest but also their breeding grounds from overdevelopment and other ruin - changes in temperature and currents, light pollution, fertilizer and sewage runoff, over sand recreational driving, and more.

Anything that can be done to preserve the natural world as untouched and unharvested as possible, I highly support. Yes, our tech billionaire overlords may have the ocean boiling in 20 years, but it's still worth pushing back against kakistocracy and oligarchy and trying to save our planet.

Thanks for your consideration and for what you do. SC

Who owns horseshoe crabs? These remarkable animals with 400 million years of history are ancient icons worthy of full protection.

Killing horseshoe crabs for profit by a few that incurs loss for the great majority of people and all of nature is simply wrong.

The evidence is clear. The trade in ocean wildlife is based on 20th century habits that have caused collapse of natural systems vital to the health of the planet including humankind. This is simply wrong.

Yielding to commercial interests, whether from fishing enterprises that profit from taking wildlife at no cost or the pharmeceutical industry with less costly synthetic alternatives available, is simply wrong,

The allowable take must be zero for creatures that are vital links in ancient ecosystems that stretch from the Arctic to Antarctica.

Why set meaningless quotas that are impossible to enforce. Just stop killing them for commerce, period.

.

I urge immediate full protection now for horseshoe crabs while recovery for these treasured animals is still possible.

It is the right thing to do,

Sincerely,

To:
Marine.Fish@mass.gov
Subject: Public Comment Supporting the End of Horseshoe Crab Bait Harvest

Dear Director McKiernan and the Division of Marine Fisheries,

I am writing as a concerned local resident of MA to ask you to end the commercial horseshoe crab bait harvest in Massachusetts. I can not be at the public hearing, so submit this comment in my stead.

I've lived here a long time, and I've seen a sad and noticeable decline in the number of horseshoe crabs present on the beaches across the Cape and the South Shore. They just aren't here like they used to be.

My concern also comes from personal experience. As a teenager working in a crab lab, I saw the blood extraction process firsthand. At the time, I didn't realize I was working for the biomedical industry. It stayed with me. Knowing that these animals are also being killed just to be used as bait—especially when HorseshoeCrabs.org notes they take over 10 years to even reach maturity—feels like a waste of a species that has been around for millions of years.

The decline of an ancient animal is a signal that should set of dashboard alarms. We should be protecting these crabs so they can continue to support our local ecosystem, including sharks and shorebirds. Please stop the bait take to give our local populations a chance to recover.

Thank you,

Heidi Aylward

Horseshoe crabs are iconic, ending up as the subject of sculpture, paintings, jewelry. They're beloved and over harvested. Where I live, the fishing industry insists there is no over harvesting, but they've said that about every challenge, ie it's not the fishermen who are to blame. Similarly, I believe they're over harvested for the biomedical industry who have little to lose by taking all they can get with the hermit crabs considered a small price to pay for their purpose, but little oversight to how they're handled.
Please end the unnecessary and unsustainable bait harvest of these creatures that are vulnerable to.
Thank you.

Dear Mr. McKiernan -

My name is Anita Ryan and I live in Hingham, MA.

My family and I have been delighted every time we see a horseshoe crab in Hingham harbor or along the Weymouth Back River in Bare Cove Park. This is a resilient yet fragile species. We urge you to protect and preserve this species for future generations.
To protect them, we need to protect their eggs and their blood and encourage companies to find synthetic alternatives that don't look upon this treasured species as a commodity.

We need good management of this species to ensure its continued survival in the coastal waters of New England.

I urge that we limit the horseshoe crab bait industry and DO NOT expand the blood-letting industry. We need to do this for this crucial and ancient animal, and let better baits and newer medical models prevail, as will happen this year in New York's newly passed legislation. This is a step we must take today to ensure that our children and grandchildren live in a future world with wonderful thriving species and biodiversity like the Horseshoe crab.

Thank you!

Anita

37 Baker Hill Drive, Hingham MA 02043

A letter to the Massachusetts Division of Marine Fisheries — at marine.fish@mass.gov (Attention: Director McKiernan) — would go a long way to help migrating shorebirds and horseshoe crabs. The ask: stop blood-letting as well as baiting. This is also a good week to reach out to Governor Healey, Representative Kassner, and Senator Tarr.

To whom it may concern:

The horseshoe crab is a vital part of our ecosystem. Like so many other species, harvesting it is unethical. We need to honor Mother Nature's plan and understand that every species has an important role in the sustenance of the whole creation of life!

For any particular species to be considered expendable for another part of the system is a serious misunderstanding of the entire biological system that was created by a force larger than we humans can comprehend.

However, we must! We must taken in the miraculous creation of all life. We must comprehend the interdependence of all life and the necessity of respecting and honoring ALL life including the horsechose crab!

Lastly it is gross to consider that profit is more important than life. It is not. It is human folly to think so. It is reprehensible that humans destroy life for their own greedy economic profit.

Respectfully submitted,
Pamela Russell

[T]he invitation of mindfulness is to drop into the actuality of experience, opening to this moment just as it is, with things exactly as they are, and then, to whatever degree possible, seeing if you can be at home with what is unfolding. In all likelihood, you will discover that your equanimity and nonreactivity are very limited, that you're going to react virtually

instantly with all sorts of thoughts, emotions, contractions in the body, with impatience, with aversion.

You might think, “Why am I meditating? I’m sure this isn’t what I’m supposed to be feeling.” Yet this is exactly what you’re supposed to be feeling. Why? Because the curriculum here is that you are staying open to feeling and recognizing whatever it is you are actually feeling. No matter how painful or disturbing it is, for at least a moment, seeing if you can hold it in awareness as a parent might hold a child, with pure love. That moment of awareness is a moment of liberation. It’s not like you have to sit for fifty years to taste moments of liberation. But it helps if you come to see life itself as the practice, and every moment as a gift.

-Jon Kabat-Zinn, founder of Mindfulness Based Stress Reduction (MBSR) and a student of Zen Master Seung Sahn of the Kwan Um School. From an interview in Lion's Roar, March 31,2025.

Date:	Monday, March 2, 2026 11:34:03 AM

CAUTION: This email originated from a sender outside of the Commonwealth of Massachusetts mail system. Do not click on links or open attachments unless you recognize the sender and know the content is safe.

Dear Director Dan McKierran:

I am Dr. David Dow, a retired marine scientist from NOAA's Northeast Fisheries Science Center-Woods Hole Laboratory and emeritus Sierra Club activist (who helped co-found the Sierra Club Cape Cod Group). I feel that the focus of the Fishery Management Plan should be ecological restoration of the horseshoe crabs and protection of their essential fish breeding habitats on coastal beaches. The bait fishery should be eliminated and the the medical catch and release fishery should be reduced to allow for catching release death rates.

I was the last NOAA Recreational Fisheries Coordinator in the Northeast and developed Essential Fish Habitat reports for some Federally managed species. I feel that the Massachusetts Ocean Management Plan and coastal Biodiversity Plan should be utilized to protect horseshoe crabs in the ocean from climate change/nutrient pollution and restore their coastal beach breeding areas on Cape Cod and elsewhere in the Commonwealth. We already face challenges in becoming Cape No Cod and I would hate to see iconic horseshoe crabs follow this pathway.

Having recently participated in a recent meeting for revision of the Massa. Ocean Management Plan (MOMP) and participated in the Biodiversity Plan dialog on Cape Cod, I feel that 3 mile ocean boundary with Federal waters and shoreline beach breeding areas which are subject to erosion from storms/sea sevel rise are not being adequately addressed by the Massa. Executive Office of Energy and Environment from an adaptive, ecosystem-based management perspective. The Sierra Club submitted an outline of this perspective in 2021 to MOMP which was ignored. Ma. DMF should operate under the revised MOMP guidelines and the state Clean Energy and Climate Action Plan for effects on fish/ shellfish populations (not just fishing and natural mortality effects on recruitment and growth).

Thanks for considering these comments.

Dr. David D. Dow
Falmouth, Maa.

From: Nicole Rivard
To: Marine Fish (FWE)
Subject: Friends of Animals opposes MA DMF"s horseshoe crab proposals
Date: Sunday, March 1, 2026 10:28:12 PM

CAUTION: This email originated from a sender outside of the Commonwealth of Massachusetts mail system. Do not click on links or open attachments unless you recognize the sender and know the content is safe.

Mass. Division of Marine Fisheries

March 1, 2026 Written Testimony

OPPOSING DMF's PROPOSAL TO:

- **Reduce the bait quota from 140,000 to 100,000 horseshoe crabs**
- **Increase the biomedical quota from 200,000 to 280,000.**

Under Massachusetts' Rent-A-Crab program, biomedical companies would also be permitted to bleed up to 100,000 bait-designated crabs before they are used as bait.

Submitted by Friends of Animals/Presented by Nicole Rivard, Government Relations Manager

It is appalling that DMF is offering Massachusetts residents this bait and switch scheme.

On behalf of Friends of Animals and our hundreds of Massachusetts members, we oppose the agency's audacity to intensify the exploitation of horseshoe crabs. Currently headquartered in CT, we led the efforts here to ban the killing of horseshoe crabs for bait or biomedical purposes—it passed in 2023. We also helped get similar legislation passed in the NY State Legislature, which was signed into law by Gov. Hochul in December.

These efforts to save horseshoe crabs from extinction may not have as big of an impact if they're still being killed in places like Massachusetts.

We do support the legislation—H. 898—that is moving through the Massachusetts legislature, which would ban the killing of horseshoe crabs for bait. It got voted out of the Joint Committee on Environment and Natural Resources and is awaiting a vote in the House. If it passes it will go to the Senate.

Fishers in Massachusetts are allowed to kill and chop up 140,000 horseshoe crabs each year for use as bait for whelk? The unnecessary, reckless practice is done so people could eat conch fritters and severely hinders the species' ability to recover.

In 2024, Massachusetts Division of Marine Fisheries issued 185 Horseshoe Crab Bait permits. The agency's data reveals that 40 fishers participated in 2024, earning a total $280,000, which means they're pushing horseshoe crabs to extinction to earn $7,000.

Massachusetts must stop myopically protecting the commercial fishing industry by allowing the reckless, unnecessary killing of any horseshoe crabs for bait so people could eat smoked eel and conch fritters.

Not to mention it's unnecessary, and frankly insane, that Massachusetts would increase the

biomedical quota. May 1 marked a pivotal shift in the biomedical industry that changes the tide for imperiled Atlantic horseshoe crabs. U.S. pharmaceutical companies are now allowed to use animal-free alternatives—the reagents rFC and rCR— in tests to detect toxic substances in injectable medicines and implants rather than the blue blood of the horseshoe crab.

Now the biomedical industry has no excuse not to stop wasting the lives of horseshoe crabs. The new standard was proposed and adopted by U.S. Pharmacopeia.

No one should be debating whether their numbers are plentiful enough to allow their commercial slaughter in the first place—it's always been scientifically and morally unjustifiable.

Dwindling numbers of horseshoe crabs along Connecticut and New York shorelines have led to their functional extinction in Long Island Sound. That means they have become too rare to fulfill their crucial, interconnected role in the ecosystem. This tragedy is unfolding in Massachusetts as well.

The low numbers of horseshoe crabs are leading to a steep decline and possible extinction of other species—such as the threatened red knot— a shorebird who depends on horseshoe crab eggs for food to fuel its epic biannual flights between the southern tip of South America and the Arctic.

In 2021, fewer than 7,000 red knots were found in the Delaware Bay, **a key spring stopover habitat**. That's less than a third found in 2020. **And red knot numbers remained at historically low levels in 2022.**

Without sufficient horseshoe crab eggs to feed on, migratory birds run out of energy and die before reaching their breeding grounds. Horseshoe crabs are also an important source of food for other wildlife such as sea turtles, and species such as anemones, barnacles, oysters, and seaweed use horseshoe crab shells as homes.

Brand new research from the Maritime Aquarium (https://www.maritimeaquarium.org/newsroom/posts/new-studies-urge-immediate-coordinated-action-for-the-protection-of-horseshoe-crabs)

in Connecticut reveals horseshoe crab populations have plummeted to "severe" levels. Immediate action is needed to prevent horseshoe crabs from going extinct, the authors say, adding that the New England area has been understudied and under protected.

The study gave researchers a comprehensive look at horseshoe crab trends not just in the Long Island Sound's offshore waters, but also in its 115 bays, harbors and coves.

Atlantic horseshoe crabs are in such dire straits that Friends of Animals and other advocacy groups have petitioned to list them under the Endangered Species Act.

Horseshoe crabs have figured out how to harmonize with the environment to last half a billion years. They deserve our respect and protection.

From: Dante Simonetta
To: Marine Fish (FWE)
Subject: Attention: Director McKiernan, Horseshoe Crab Input
Date: Sunday, March 1, 2026 5:54:08 PM

CAUTION: This email originated from a sender outside of the Commonwealth of Massachusetts mail system. Do not click on links or open attachments unless you recognize the sender and know the content is safe.

Dear Director McKiernan,

I am writing as a Massachusetts resident to comment on the proposed changes to the horseshoe crab quotas for 2026.

Since moving to the United States, I've fallen in love with the coastal wildlife here. Horseshoe crabs in particular have become incredibly meaningful to me. There's something grounding about seeing a species that has existed for hundreds of millions of years still making its way onto our beaches. They feel like part of the identity of this place.

Over the past few seasons, I've spent time watching them spawn. What I've noticed has been hard to ignore. Horseshoe crabs used to mate in pairs, but now it's common to see multiple males stacked onto a single female. That change feels significant. It suggests imbalance. When crabs are removed from spawning beaches before they lay eggs, there is no guarantee they will successfully reproduce later. Disrupting that process works against recovery.

That's why I'm deeply concerned about the proposal to increase the biomedical quota from 200,000 to 280,000 crabs, especially when up to 100,000 bait crabs may also be routed through the Rent A Crab program for bleeding. At the same time, the Division has acknowledged that bait demand is closer to 75,000 to 90,000 crabs annually. Expanding total take in this context feels unnecessary and out of step with the moment we are in.

Neighboring states are choosing a different path. New York has passed a three year moratorium on commercial horseshoe crab harvest for both bait and biomedical purposes. Connecticut has also taken stronger conservation measures. Massachusetts has the opportunity to lead here, not lag behind.

I understand that biomedical companies rely on horseshoe crab blood, but synthetic alternatives exist and are increasingly being used. Bait demand is declining. We could also shift more fully toward alternative bait sources such as green crabs. This seems like a moment to reduce pressure and allow populations to rebuild, not expand harvest.

Horseshoe crabs are not just a commodity. They are part of a fragile coastal ecosystem and a public resource that belongs to all of us. I respectfully urge the Division to maintain the existing 200,000 biomedical cap and reconsider the scale of the bait quota rather than increasing overall exploitation.

Thank you for taking the time to consider public input on this important issue.

Dante Simonetta, Provincetown MA.

Mar 1, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Thank you for your time!

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

26 February 2026

Dear Dr. Petitpas,

Massachusetts Division of Marine Fisheries
Dear Director McKiernan,
Horseshoe crab eggs are a crucial resource for global migratory birds, and rare shorebirds including the Red Knot have been seen feeding on them at Monomoy, where horseshoe crab harvest is forbidden. Shorebirds are among the most rapidly declining group of birds, while I have enjoyed observing them for many years, in Massachusetts and other regions along their epic global migratory journeys. It would be devastating to think that we would not act to maintain the ability of residents of Massachusetts to enjoy these and several other shore bird species.
While the new proposed rule is a step in the right direction and therefore urgently needed as the migration will soon begin again, I urge you to also consider banning their harvest for any purpose until numbers are restored and stable. At such a point the active monitoring and management of the horseshoe population might allow limited harvest for legitimate purposes where alternatives are not available. Harvests for biomedical research are no longer valid as synthetic blood products are now widely available.
Many thanks for taking the immediate necessary action to protect the horseshoe crab and all those other species that depend upon it, and on behalf of those who love nature and birds.

Sincerely,
Mark Hibberd MD PhD

I am concerned that this year's DMF proposed horseshoe crab quotas **expands biomedical exploitation; maintains bait quotas that exceed actual need; puts Massachusetts out of step with neighboring states; and ignores unresolved concerns about population recovery.**

The proposed quotas prioritize private commercial interests over long-term population recovery, ecosystem health, and resilience.

Please propose quotas that reduce horseshoe crab exploitation and promote long term population recovery.

Thank you,
Judy Belaval

Director McKiernan:

Why are we here?

Why, when there is agreement in the scientific community – outside the State House - that the present Massachusetts regulations governing the harvest for horseshoe crabs are outdated and ineffective, are we debating another half-measure?

A bill to end all taking of horseshoe crabs for bait – in Massachusetts – House Bill 898, is presently under consideration by the Massachusetts legislature.

Testimony in support of that bill, was submitted by many important conservation organizations, marine biologists and scientists, including a Nobel Laureate.

Just three months ago Mass Audubon's director of Legislative and Government Affairs, Sam Anderson, offered a wonderfully succinct argument for the immediate and complete halt to the bait harvest.

The message is clear, Anderson wrote: "Ending the horseshoe crab bait harvest will not harm the biomedical industry." The state's Division of Marine Fisheries," he continued, "is already working with biomedical companies to secure a supply of crabs separate from the bait fishery. Meanwhile the industry is transitioning to synthetic endotoxin testing, which eliminates the need for horseshoe crab blood.

"Both biomedical horseshoe crab bleeding firms in Massachusetts already sell their own synthetic versions of the test," Anderson noted.

The bait harvest, Anderson concluded, is outdated, unnecessary and deeply unpopular.

It's too late for the state to show leadership in this area, but can we at least follow the examples of Delaware, New Jersey, New York and Connecticut?

To quote famous Boston Celtic announcer, Johnny Most, "stop fiddling and diddling." End the bait take!

Dear Director McKiernan,

Horseshoe crabs are vital to the survival of many species, including threatened and endangered bird species. The overall " take" of horseshoe crabs needs to be substantially decreased. There are well recognized alternatives to the use of horseshoe crab blood for biomedical purpose.

Please lower the "take" of horseshoe crabs in the new regulations.

Thank you,

Sal Insogna

Dear Director McKiernan,

The Massachusetts Society for the Prevention of Cruelty to Animals (MSPCA) urges rejection of the proposed increase in the biomedical harvest quota for horseshoe crabs.

As you know, the horseshoe crab populations faces significant pressure from biomedical and commercial harvesting, and the process used to produce Limulus amebocyte lysate (LAL) by bleeding causes both mortality and sublethal impacts. There are approved non-animal alternatives, such as recombinant Factor C (rFC) and recombinant Cascade Reagents (rCR).

Horseshoe crabs are a keystone species; their eggs feed migratory shorebirds and support coastal ecosystems. Increasing the quota would further strain this already declining species and the coastal environment. The availability of non-animal alternatives eliminates any need to expand the harvest.

We request the Division to reject the proposed quota increase and prioritize conservation.

Thank you,
Kara Holmquist

Feb 27, 2026

Director Daniel McKiernan

Dear Director McKiernan,

I write in support of DMF's proposal to reduce the annual bait harvest quota for horseshoe crabs and increase the allowed biomedical harvest, which will have the effect of reducing the number of horseshoe crabs killed.

Overall, the proposal could save 28,000 horseshoe crabs annually, which is a step toward putting the population back on track for a recovery. But given the ecological, cultural, and economic importance of horseshoe crabs, the outdated and unnecessary harvest of these animals to be used as bait in an unsustainable conch fishery needs to be phased out completely.

Both as a veterinarian and a Massachusetts resident, I am deeply concerned about preserving our coastal resources, if not restoring them to pre-exploitation states. The importance of horseshoe crabs and their spawning cycles in the ecosystem has been long overlooked and abused by short-sighted anthropocentric policies. It is critical that the DMF adopt these changes if there is any hope of preserving the horseshoe crab population for the future, either as a resource for exploitation or as a step toward restoration of natural habitat.

Please proceed with adopting these changes in the harvesting regulations, and pursue further steps toward recovery of this species to historic population levels.

Sincerely,

Dr. Charles Byrd

Subject: Urge you to reduce Horseshoe Crab quotas

CAUTION: This email originated from a sender outside of the Commonwealth of Massachusetts mail system. Do not click on links or open attachments unless you recognize the sender and know the content is safe.

Dear Director McKiernan,

I am writing to urge you to limit the bait and biomedical quotas for horseshoe crabs. The current proposal increasing those quotas are unnecessary.

This proposal puts Massachusetts out of step with neighboring states; and ignores concerns about population recovery.

The DMF's own proposal states that "the current local bait crab demand approximates 75,000-90,000 horseshoe crabs annually" — an explicit acknowledgment that the proposed bait quota exceeds actual bait

Bait demand is declining due to the collapse of the whelk fishery, and biomedical companies are increasingly transitioning to a synthetic alternative to horseshoe crab blood.

The DMF should be instead reducing quotas and focusing on rebuilding horseshoe crabs populations in the state. Our survival as a species depends on our ecosystem health.

As elder citizens, we are deeply concerned about preserving biodiversity for a healthy, sustainable, livable future for all.

Respectfully,

Ginger Ryan and Peter Kelsey

Dear Daniel McKiernan,

Regarding:
"6. Commercial Horseshoe Crab Quotas (322 CMR 6.34). In response to changing demand for horseshoe crabs, DMF proposes to: a. Reduce the annual horseshoe crab bait quota by 40,000 crabs thereby moving it from 140,000 crabs to 100,000 crabs. b. Reallocate these 40,000 crabs to the biomedical quota at a 1:2 ratio thereby increasing the annual biomedical quota from 200,000 crabs to 280,000 crabs."

I agree with reducing the bait catch quota of horseshoe crabs.

I disagree with increasing the biomedical research quota.

To fight against 'shifting-baseline-syndrome', I would ask:
Are the horseshoe crabs at pre-European contact levels?
If not we should reduce all take until the populations have rebounded to the levels they were before the1600s.

As I'm sure you are aware, horseshoe crabs play a critical role in the ecosystem. There are endangered migratory shorebirds and a myriad of other animals that rely on horseshoe crab eggs for essential, basic sustenance. Their ecological contributions need to be THE primary and protected value we assign to them.

Thanks for the opportunity to comment.
