

# Restructuring traditional biotoxin monitoring programs for proactive management of new and emerging threats

Kohl Kanwit – Director, Bureau of Public Health

[www.maine.gov/dmr](http://www.maine.gov/dmr)

# What biotoxin in Maine used to mean

- ▶ Biotoxin was synonymous with red tide/PSP/saxitoxin
- ▶ Decades of experience
- ▶ Predictable season from March to October
- ▶ Predictable hot spots
- ▶ Established sampling stations
- ▶ Species specific responses
- ▶ HPLC PCOX method provides early warning

# What we didn't know.....

- ▶ Red tide was easy!

- ▶ Use historic information to inform strategy, sample between March and October, monitor phytoplankton, test shellfish, close, open, relax till the following March

# .....What we know now

- ▶ The Gulf of Maine now has PSP and ASP
- ▶ Maybe DSP but definitely *Dinophysis norvegicia*
- ▶ We also have other HAB species that impact marine organisms but not necessarily human health
- ▶ *Karenia mikimotoi* first showed in 2017 and can cause anoxic conditions as well as toxic effects on fish and shellfish
- ▶ *Margalefidinium* (previously *Cochlodinium*) *polykrikoides* first showed in 2016 and can cause anoxic conditions as well as toxic effects on fish and shellfish

# Why mention HABs that don't impact human health?

- ▶ Guess who the Commissioner calls when the Marine Patrol pilot sees this:

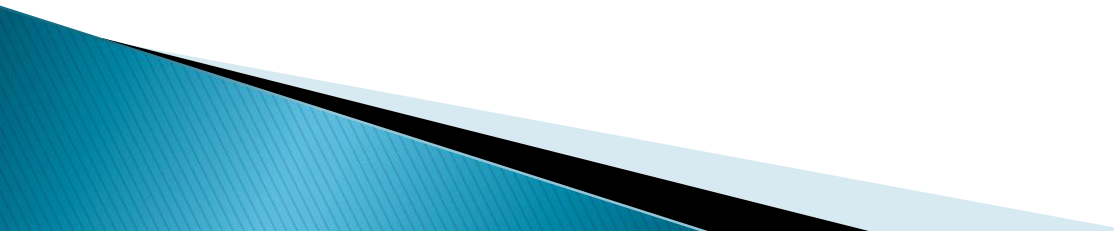

Or when the public sees this on the Portland waterfront:

# Questions that are asked

- ▶ Telling the Commissioner we only look for HABs that affect human health isn't the "right" answer.
  - ▶ Will these blooms affect aquaculture farms?  
yes, maybe
  - ▶ Will these blooms affect wild shellfish resources?  
yes, documented clam kills
  - ▶ Will these blooms affect fish?  
yes, maybe
- 

# No one wants this to happen

Restructuring traditional biotoxin  
monitoring programs for proactive  
management of new and emerging  
threats

# Programmatic changes

- ▶ Monitor phytoplankton samples for these species as well as HABs that affect human health
- ▶ Alert management and industry when blooms are observed
- ▶ Identify/monitor visible blooms
- ▶ Monitor DO
- ▶ **Additional burden on staff resources**

# Blah blah blah ASP

- ▶ *Pseudo-nitzschia* present in the Gulf of Maine since.....forever?
- ▶ Toxin present in 2012
- ▶ No toxin measured above limit in Maine until 2016
- ▶ Identification of *P. australis* in GOM in 2016
- ▶ Toxin measured above the limit in 2016, 2017 and 2018

# ASP is NOT like PSP

- ▶ Decades of experience
- ▶ Predictable season from March to October
- ▶ Predictable hot spots
- ▶ Established sampling stations
- ▶ Species specific responses
- ▶ HPLC PCOX method provides early warning
- ▶ Nope (3 years and counting)
- ▶ Nope (year-round)
- ▶ Nope (or maybe?)
- ▶ Nope (continually adapting)
- ▶ Nope (or maybe?)
- ▶ HPLC UV method also provides early warning

PSP

ASP

# Worst case scenario

- ▶ Shellfish seem to exceed the ASP limit quickly when conditions are right
  - ▶ Testing frequency can't keep up with increases in toxicity
  - ▶ In 2016 and 2017, closures were implemented after samples exceed ASP limit and recalls were necessary
  - ▶ Felt like worst case, but really worst case would be an illness outbreak which we avoided
  - ▶ **Recalls work**
- 

# Restructuring traditional biotoxin monitoring programs for proactive management of new and emerging threats

# Programmatic changes (ASP)

- ▶ Year-round phytoplankton sampling
- ▶ Qualify cell type (LG v. SM)
- ▶ Low LG cell/L trigger
- ▶ Presence/absence toxin test on phyto
- ▶ Once phytoplankton samples show presence of toxin, meat sampling begins
- ▶ Presence of measurable toxin in shellfish triggers precautionary closures
- ▶ **Protect public health and avoid recalls**

# More programmatic changes (ASP)

- ▶ Significance of regional mussel closures
- ▶ No sampling of non-commercial species
- ▶ Biotoxin MOUs (not for LPAs)
- ▶ Industry phytoplankton samples required
- ▶ Mandatory education for LPAs
- ▶ Manage the burden on staff and budget resources

# Explaining the phyto component

- ▶ We are not regulating on phyto counts
  - That's only allowed in the NSSP MO for *K. brevis*
- ▶ Not all *Pseudo-nitzschia* makes toxin and only some species make toxin sometimes
- ▶ We use phyto to inform frequency and timing of shellfish meat testing
- ▶ If phyto is not making toxin there is no need to do more expensive meat testing

# Explaining precautionary closures

- ▶ For ASP this seems to be the best way to avoid recalls
- ▶ Very disruptive to industry
- ▶ Difficult to communicate
- ▶ Strains staff and budget resources
- ▶ Moving forward:
  - predictable closure periods
  - Increased sample processing capability

# And then there's DSP

- ▶ Or is there?
- ▶ Blooms of *Dinophysis norvegica*
- ▶ 2016 and 2018 phosphatase inhibitor assay (PP2A) showed toxicity >regulatory limits
- ▶ Approved LCMS method did not show toxicity >regulatory limits

# So what do you do?

- ▶ Closed area for 3 months
- ▶ Closed based on PP2A, reopened with PP2A
- ▶ FDA found new toxin that explains conflicting results between methods
- ▶ Unknown if new toxin has a human health impact

Restructuring traditional biotoxin  
monitoring programs for proactive  
management of new and emerging  
threats

# Stick with the program

- ▶ Going forward use the approved LCMS method
- ▶ Supported ECOHAB proposal for investigating this problem
- ▶ Collect and purify toxin
- ▶ Conduct mouse testing to determine toxic effects
