Frank’s Lovegrass

**Eragrostis frankii** Meyers.

State Status: **Special Concern**
Federal Status: **None**

**DESCRIPTION:** Frank’s Lovegrass is an annual grass with repeatedly branched, erect culms, 1-3 dm high. The narrow blades are 5-13 cm long and 1-3 mm wide. The tiny spikelets are ovate and typically 3-5 flowered. The flowering season is August-September.

**SIMILAR SPECIES:** Nine other species of *Eragrostis* are recorded from Massachusetts. The following species are from the same habitat as *E. frankii*: *E. hypnoides*, *E. pestinia*, *E. pilosa*, and *E. cilianensis*. Frank’s Lovegrass can be told from all of them by the combination of erect plants, long-elliptic inflorescences usually one-half the height of the plant, tiny spikelets with only three to five flowers or fruits, and second glumes as long as the lowest lemma.

**HABITAT:** This species prefers sandy riverbanks and sandbars. In Massachusetts, it has been found only along the Housatonic and Connecticut Rivers.

**RANGE:** This grass is distributed from Southern New Hampshire to Minnesota, south to Florida, Louisiana, and Oklahoma.

**POPULATION STATUS:** Frank’s Lovegrass is currently listed as a Species of Special Concern in Massachusetts. Eighteen current (1984 to present) occurrences have been verified, and three additional historical occurrences are reported.
